1. List of acronyms and glossary

AGB – above ground biomass: All biomass of living vegetation, both woody and herbaceous, above the soil including stems, stumps, branches, bark, seeds, and foliage - IPCC (2006)

AD – activity data: data on the magnitude of a human activity resulting in emissions or removals taking place during a given period of time. Data on land areas, management systems, fertilizer use are examples of activity data - IPCC (2006)

BGB – below ground biomass: All biomass of live roots. Fine roots of less than (suggested) 2mm diameter are often excluded because these often cannot be distinguished empirically from soil organic matter or litter - IPCC (2006)

COEAM – INPE's Amazon Space Coordination (Portuguese acronym)

CCST – INPE's Earth System Science Center (Portuguese acronym)

EBA: Portuguese acronym for CCST Project "Improvement of biomass estimation methods and models of estimation of emissions by land use change"

DIOTG – INPE's Division of Earth Observation and Geoinformatics (Portuguese acronym)

DW – dead wood: Includes all non-living woody biomass not contained in the litter, either standing, lying on the ground, or in the soil. Dead wood includes wood lying on the surface, dead roots, and stumps, larger than or equal to 10 cm in diameter (or the diameter specified by the country) - IPCC (2006)

DETER – INPE's Real-Time Deforestation Detection System (Portuguese acronym)

Disordered logging: for the purposes of this submission, disordered logging refers to logging activities in natural forest land that has a disordered (irregular) pattern, most likely from illegal logging activities

EF – emission factor: a coefficient that quantifies the emissions or removals of a gas per unit activity - IPCC (2006)

Forest Degradation: for the purpose of this submission, forest degradation refers to reduction of carbon stocks in forest land remaining forest land in the Amazon biome due to fire on managed forest land and disordered logging

FRA – Global Forest Resources Assessments

GTT MRV REDD+ – Working Group of Technical Experts on REDD+ for MRV (Portuguese acronym)

INPE – National Institute for Space Research (Portuguese acronym)

LI – litter: Includes all non-living biomass with a size greater than the limit for soil organic matter (suggested 2 mm) and less than the minimum diameter chosen for dead wood (e.g. 10 cm), lying dead, in various states of decomposition above or within the mineral or organic soil. This includes the litter layer as usually defined in soil typologies. Live fine roots above the mineral or organic soil (of less than the minimum diameter limit chosen for below-ground biomass) are included in litter where they cannot be distinguished from it empirically - IPCC (2006)

MMA - Ministry of Environment (Portuguese acronym)

MMU - Minimum mapping unit: the smallest size that determines whether a feature is captured from a remotely sensed image

NDVI – Normalized Difference Vegetation Index

PAMZ+ – Amazon and Other Biomes Monitoring Program (Portuguese acronym)

Phytophysionomies: refer to the type of vegetation present in a given biome. In each biome or region that are predominant phytophysionomies or vegetation

PRODES – INPE's Monitoring Program of the Brazilian Amazon Forest by Satellite (Portuguese acronym)

SINAFLOR – National System of Forest Products Origen Control (Portuguese acronym)

SRTM – Shuttle Radar Topography Mission

TACC – transparency, accuracy, completeness, and comparability

TerraClass – Land Use and Occupation Mapping System Project (Portuguese acronym)

2. Introduction

Brazil welcomes the opportunity to submit a **national forest reference emission level (FREL)** for a technical assessment under the United Nations Framework Convention on Climate Change (UNFCCC), in the context of results-based payments for reducing emissions from deforestation and forest degradation and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries (REDD+).

Brazil has indicated in previous submission that its national FREL would be the sum of the FRELs for each of its six biomes. This submission represents **Brazil's national FREL**.

Brazil underlines that the submission of FRELs and/or Forest Reference Levels (FRLs) and subsequent Technical Annexes to the Biennial Update Report (BUR) and Biennial Transparency Report (BTR) with REDD+ results attained are voluntary and exclusively for the purpose of obtaining and receiving results-based payments for REDD+ activities, pursuant to decisions 13/CP.19, paragraph 2, and 14/CP.19, paragraphs 7 and 8¹ and does not interfere with the Nationally Determined Contribution (NDC) submitted by Brazil to the Paris Agreement.

3. Information used in the construction of Brazil's national FREL

3.1. Brazil's biomes

Brazil's national FREL covers all six biomes in the country:

- **Amazon:** The Amazon biome is formed mainly by forest formations, with the occurrence of small enclaves of savanna and grassland formations. Considered the largest tropical forest in the world, the phytophysionomies of the Amazon store a large amount of carbon (ARAGÃO et al., 2014).
- **Cerrado:** The second largest Brazilian biome, the Cerrado is characterized by a marked seasonal distribution of precipitation (with two well-defined seasons: dry and rainy), which results in vegetation adapted to water stress and fire conditions (RIBEIRO; WALTER, 2008). Cerrado phytophysionomies present high environmental heterogeneity (natural grasslands, shrubs and forest formations), resulting in a high rate of endemism and species diversity, which, together with the strong conversion pressure on natural habitats, has placed the Cerrado among the hotspots global biodiversity (MMA, 2002)
- **Caatinga:** The main type of vegetation in the Caatinga is the steppe savanna, represented by different physiognomic formations (forested, arboreal, parks, grassy-woody) and contact formations, forming mosaics that are influenced by the local topography and geomorphology. Other phytophysionomies occur in reduced areas (less than 15% of the biome), due to altitude and proximity to other biomes, such as

¹ Available at: <https://unfccc.int/sites/default/files/resource/docs/2013/cop19/eng/10a01.pdf>

the Atlantic Forest and the Cerrado (MCTI, 2015). The heterogeneity of the vegetation (LUETZELBURG, 1922-23; DUQUE, 1980; ANDRADE-LIMA, 1981) and the variability of rainfall and water stress give the biome high levels of diversity and endemism of fauna and flora (LEAL et al., 2005). In the Caatinga, the irregularity of the rains and the long periods of drought directly impact the survival of the population and agricultural production indices, and the accentuation of the desertification process is identified as one of its main vulnerabilities

- **Atlantic Forest:** The Atlantic Forest is mainly characterized by forest formations, although there are areas of fields, savannas, sandbanks and mangroves (Atlas dos Remanescentes Florestais da Mata Atlântica – technical report, 2019). The Atlantic Forest is also considered a biodiversity hotspot due to habitat loss and fragmentation, high rates of endemism and the large number of endangered species. Due to its history of use and occupation since the colonial period, it is the biome that has the lowest percentages of its original vegetation, despite the increase in regenerating areas (Fundação SOS Mata Atlântica/INPE, 2019). Much of the original area of the biome has given way to agricultural crops, development of industries, oil extraction centers, port areas and it is where most of the country's population live, placing the Atlantic Forest as responsible for 80% of the national GDP (IBGE, 2012).
- **Pampa:** The Pampa is mainly characterized by the presence of grassland formations, although there are forest phytophysionomies (gallery forests) and rocky outcrops. Currently, approximately 51% of the original vegetation of the grasslands has been lost due to anthropic activities, occupation and economic use (HASENACK et al., 2007). Another point that highlights the uniqueness of the Pampa is related to the heterogeneity of characteristics due to the peculiarity of the vegetation, soils and geological and geomorphological conditions, hydrological aspects and climatic order (BOLDRINI et al., 2010).
- **Pantanal:** According to POTT & SILVA. (2016) and SILVA et al. (2021), nowadays it is recognized that the Pantanal Biome is composed of the intersection of four large phytoecological regions: Seasonal Deciduous Forest, Seasonal Semideciduous Forest, savanna (Cerrado), and Steppic savanna (Chaco). This Biome also contains elements of Ombrophylous Forest, typical of the Amazon. In addition, there are the floristic contacts and the pioneer (early successional) formations. The dynamics of flooding in the Pantanal is related to the precipitation of a large amount of water (between December and January) in the Central Plateau region of the Cerrado biome and its consequent flow to the floodplains, where it forms lakes, swamps and marshes, resulting in flooding of part of its extension (PADOVANI, 2017).

*The area of each biome was defined according to the “Map of Biomes and Coastal-Marine System of Brazil” (IBGE, 2019), that have established new boundaries for the six Brazilian biomes, compatible with the scale of 1:250,000. **Figure 1** presents the*

map with the geographical distribution of the Brazilian biomes, developed by IBGE, in 2019. **Table 1** shows the geographic area covered by each biome, and the corresponding percentage contribution to the total national area (IBGE, 2019).

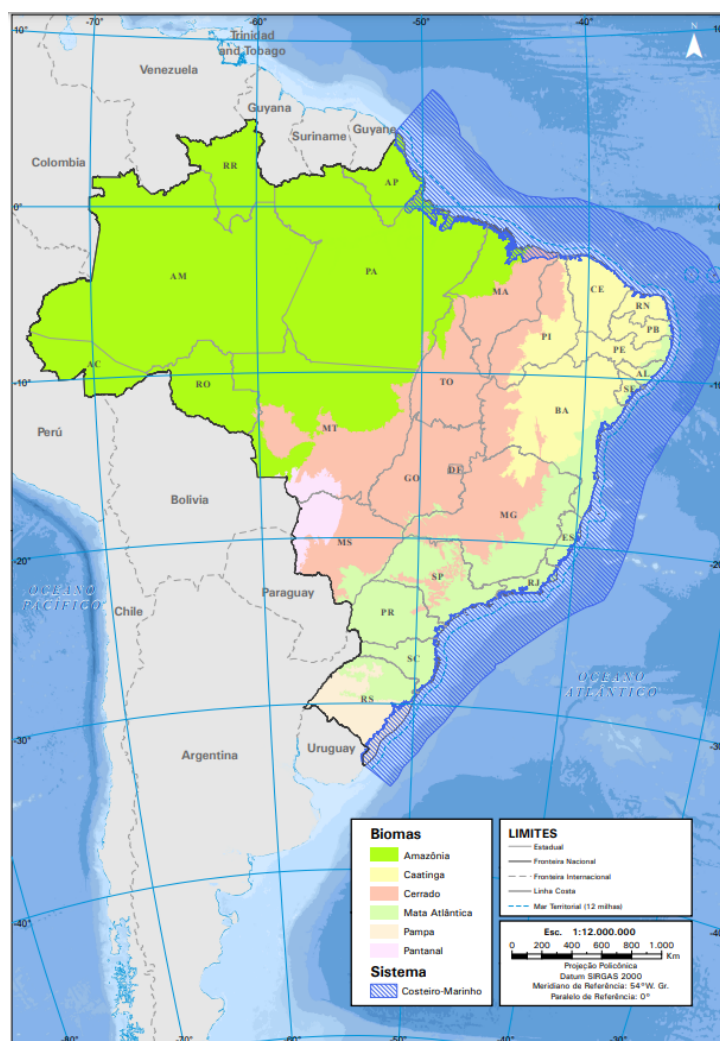

Figure 1 –Biomes and Coastal-Marine System Map of Brazil

3.2. Forest definition

For the purpose of this submission, the **forest definition** adopted is the same as that used by Brazil in its latest GHG inventory (hereinafter referred to as "4th National GHG Inventory" - Brazil, 2020) and in its "Global Forest Resources Assessment - FRA" (FAO, 2020). The definition is reproduced below:

"Minimum area of 0.5 hectares with trees of minimum height of 5 meters and minimum canopy coverage of 10 percent, or trees capable of reaching these limits in situ. Does not include areas predominantly used for agricultural or urban purpose".

Forest area, as defined above, comprise those areas with predominance of tree species and a continuous or discontinuous canopy formation. Given this comprehensive definition, forest formations comprise various types of various phytophysionomies in the different Brazilian biomes (Figures 2 to 7). Brazil's national FREL adopts the official classification system for native vegetation of Brazil (NFMA - IBGE, 2012) and the categorization of these phytophysionomies, whether forested or not, is consistent with the 4th National GHG Inventory and the FRA (**Table 2**).

Table 2 – Phytophysionomies used in Brazil's national FREL

3.3. Managed forest land

Brazil have followed the IPCC “managed land proxy” in all its national GHG inventory, as well in this submission to determine the anthropogenic GHG emissions related to forest land.

According to the 4th National GHG inventory **managed forests** are “natural forests, where human action did not cause significant changes in characteristics, classified based on the map of past natural vegetation and on its phytophysionomies. It is in a protected area (Conservation Unit - UC or Indigenous Lands - TI) and, therefore, its CO₂ removals are accounted for, based on a scientific survey, when they remain with the same coverage between the evaluated periods”; and **unmanaged forests** are “natural forests, where human action did not cause significant changes in characteristics, classified based on the map of past natural vegetation and on its phytophysionomies. Emissions and removals are only accounted for when converted to anthropogenic use. CO₂ removals are not counted when it remains intact between the periods evaluated since there is no anthropic intervention” (Brazil, 2020).

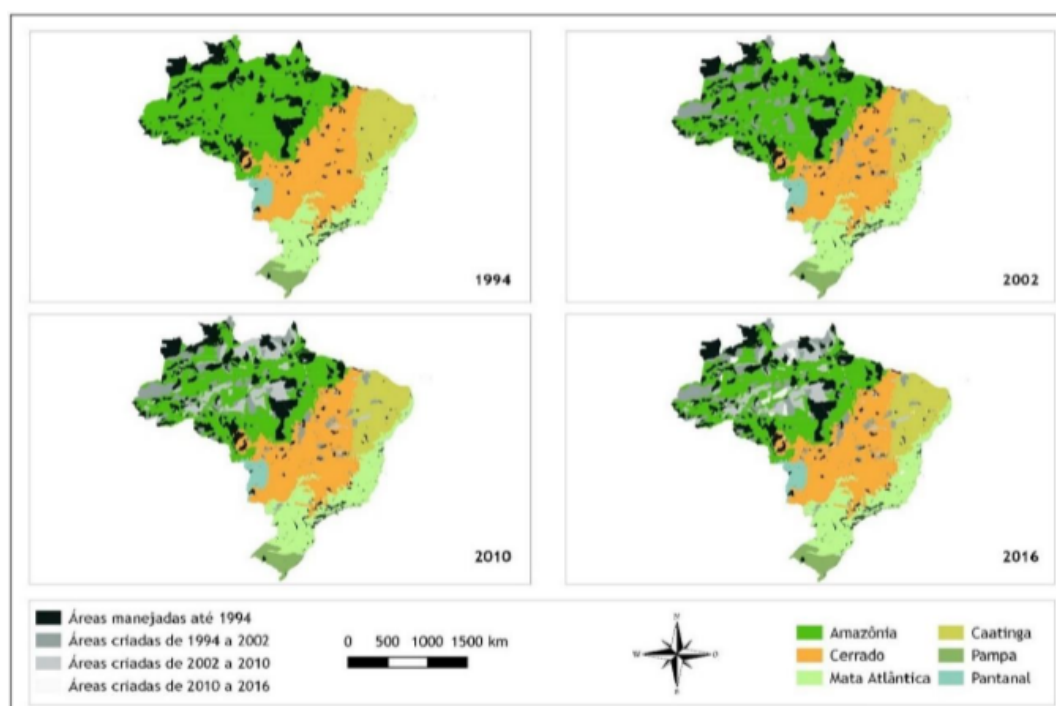

Figure 8 – Managed Forest land

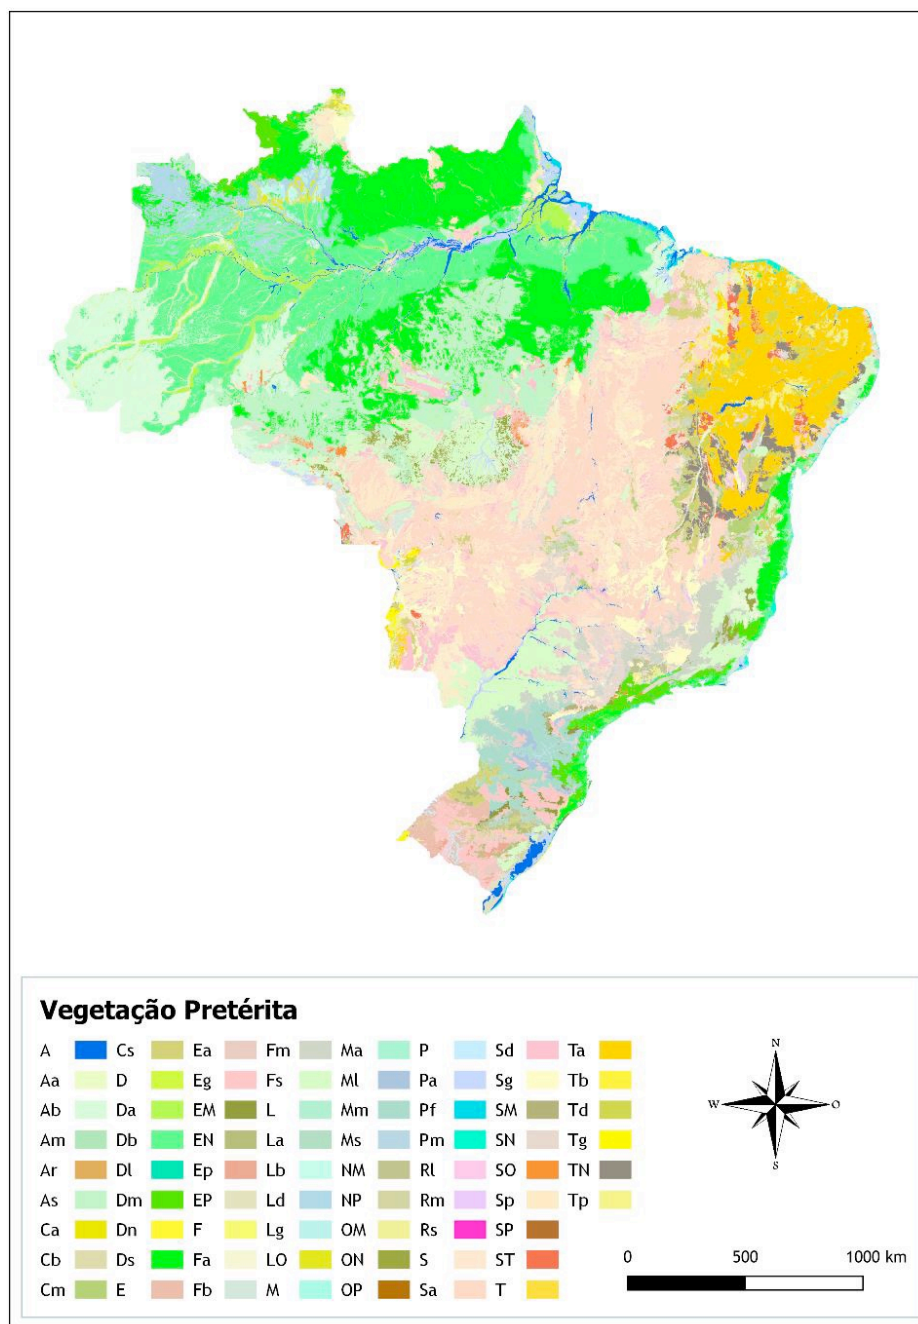

OBS: In black, managed lands created until 1994; in dark grey, areas created from 1994 to 2002; in light grey, areas created between 2002 and 2010; and in white, areas created from 2010-2016.

Source: Brazil, 2020

3.4. Ancient native vegetation map and EBA

The ancient native vegetation map used in this submission, for the purpose of phytophysiognomies identification (classification), was the same as that used in the context of the 4th National GHG Inventory (**Figure 9**). The map shows phytophysiognomies according to the IBGE classification system and the categories – forest or not forest – according to the 2020 “Global Forest Recourses Assessment - FRA”. See **Box 1** for a brief description of the methodology applied to develop the “ancient native vegetation map”.

In addition to the ancient native vegetation map, more recent estimates of biomass data for the Amazon (EBA, for the acronym in Portuguese), developed by the Earth System Science Center from the National Institute of Space Research (CCST/INPE, for the acronym in Portuguese) were also used. See **Box 2** for a brief description of “EBA”.

595
596

597 **Figure 9 – Ancient native vegetation map**

598 Source: Brazil, 2020

Box 1 – Brief description of the methodology applied to develop the “ancient native vegetation map”

“The 4th National GHG Inventory had a more up-to-date and accurate basis for the development of a map of ancient natural vegetation (i.e., distribution and classification of the various phytophysionomies, disregarding the intervention and human occupation) for all Brazilian biomes. This basis was the result of the vegetation map provided by IBGE (2017), with adjustments made by the Brazilian Forest Service (SFB, for the acronym in Portuguese) for the anthropized areas (Brazil, 2019); comparisons with the map of natural vegetation used in the 3rd National GHG Inventory (MCTI, 2015 and Brazil, 2016); and details of predominant phytophysionomies using secondary databases, as described below.

To verify the compatibility between the maps produced by IBGE, the SFB and the 3rd National GHG Inventory, analysis of the intersection between these maps was conducted, resulting in a single shapefile consisting only of the common areas among them. Subsequently, the phytophysionomies classes, described in the Technical Manual of Brazilian Vegetation (IBGE, 2012), were associated.

For some of the areas currently anthropized, the SFB classified the phytophysionomies only in relation to the dominant class. Therefore, for the 4th National GHG Inventory it was decided to cross-reference this information with other environmental databases to obtain a more detailed classification. For example, to classify the alluvial forests, hydrological data from the National Water Agency² were used, by identifying polygons with fluvial influence and cross-checking them with watercourses and artificial water masses vector files. To classify phytophysionomies in relation to altitude, the 4th National GHG Inventory used the altitude data of Shuttle Radar Topography Mission - SRTM (NASA, 2019).

Thus, the ancient natural vegetation map of the 4th National GHG Inventory is the result of a combination of sources and processing of geospatial data from different maps from IBGE (2017), SFB and the 3rd National GHG Inventory (MCTI, 2015 and Brazil, 2016)”.

² Available at: <http://metadados.ana.gov.br/geonetwork/srv/pt/main.home?uuid=2fb4464c-fc83-41d0-b63a-d020395a4a99>

Box 2 – Brief description of EBA³

“The Earth System Science Center from the National Institute for Space Research (CCST/INPE) aims at supporting and directing research to improve the accuracy of biomass and carbon estimation in the Amazon biome. Ometto et al. (2014) compared some of the biomass maps available for the region and concluded that there are significant differences between them. Nevertheless, the carbon stock estimated by the different methodologies can be considered similar due to the high uncertainty of the estimated values. Consequently, this uncertainty is propagated to the estimated carbon dioxide emissions of the country.

Given the differences found in the biomass maps available for the Brazilian Amazon and the uncertainties associated with the methods that enabled their estimation, the CCST/INPE sought to invest in technologies that could contribute to the reduction of these uncertainties.

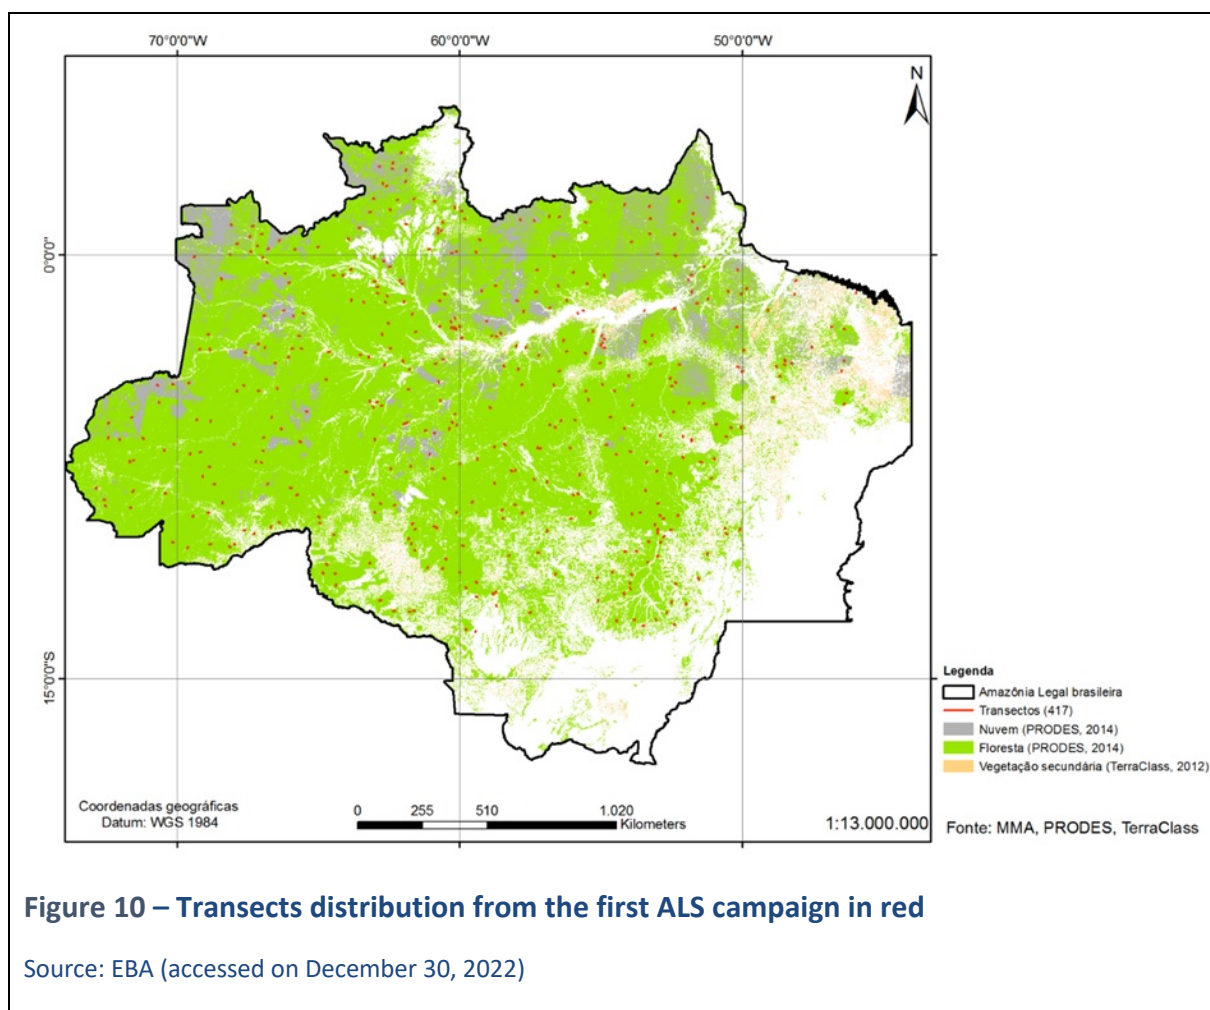

Studies indicate that, in addition to the use of forest inventory data, airborne laser data (ALS, acronym in English) can contribute to the increase of the sampled area and make it possible to extract metrics about the structure and height of the forest canopy (ASNER et al., 2012; ASNER & MASCARO, 2014).

Thus, the CCST/INPE, with the support of the Amazon Fund and resources from the National Development Bank (BNDES for the acronym in Portuguese), implemented a project referred to as “Improvement of biomass estimation methods and models for the estimation of emissions from land use change”.

The aero survey covered transects with a width of 300 m and length of 12.5 km (375 ha), with no overlap between the flight ranges. Initially, the transects were randomly selected within forest areas of the Amazon biome, disregarding areas mapped by PRODES (2014), but considering secondary forest areas identified by TerraClass (2012). Some of these transects were directed to cover areas with forest inventory plots.

In the flight campaign, data from 417 transects (**Figure 10**) were collected, covering 156,522 ha”.

3.5. Pools, gases, and activities included in Brazil’s national FREL

The following table summarizes the carbon pools, greenhouse gases (GHG) and REDD+ activities that have been included in the national FREL. Exclusions and/or omissions and future potential improvements are explained in section 0.

Table 3 – Pools, gases and activities included in Brazil’s national FREL

| Biome/information | Amazon | Cerrado | Caatinga | Pantanal | Atlantic forest | Pampa |
|-------------------|---|--------------|----------|----------|-----------------|-------|
| REDD+ activities | Deforestation (Minimum mapping unit of 1 hectare) | | | | | |
| | Degradation (Minimum mapping unit of 3 hectare) | Not included | | | | |
| | <u>Not included in this submission:</u> Conservation of forest carbon stocks Sustainable management of forest Enhancement of carbon stocks | | | | | |

| | Litter (LI) | | | | | |
| | Dead wood (DW) | | | | | |
| GHG | CO ₂ | | | | | |
| | CH ₄ | | Not included | | | |
| | N ₂ O | | Not included | | | |

The **definition of deforestation** adopted by the National Policy on Climate Change refers to the conversion of natural areas to other land-use categories. For the purpose of this submission and consistent with previous FRELS submissions, the definition of deforestation is more restrictive. It only includes the **conversion of native forest phytophysiological types into other land use categories (non-forest land)**. Consequently, different estimates of deforestation could be found for each biome if a different definition would be applied (more information can be found in section about “Consistency”). The deforestation activity data (deforestation areas) are obtained from the **PRODES Program**⁴. Additional information related to the deforestation activity data used in this submission can be found in section 8.1.

For the Amazon and Cerrado biomes, emissions from deforestation are net emissions, i.e., they are the result of the difference between the gross emissions from deforestation and the **removals from the natural regeneration of areas previously deforested (secondary vegetation)**. Data to estimate removals were obtained from the **TerraClass Project**^{5 6}. Additional information regarding secondary vegetation data can be found in section 8.3 and **Box 4**.

In Brazil, deforestation in the Amazon and Cerrado is typically followed by biomass burning (“slash and burn” - **Figure 11**). Therefore, non-CO₂ emissions for Amazon and Cerrado biomes were considered in the construction of the national FREL.

636 Source: INPE

637

638 Presently, there is not a single **definition of forest degradation** applied in the country, nor
639 the identification of all potential drivers of forest degradation (e.g., fire, logging, invasive
640 species, etc.). Due to lack of a complete database related to all potential drivers, for the
641 purpose of this submission Brazil assumes forest degradation as the **reduction of carbon**
642 **stocks in forest land remaining forest land** in the Amazon biome due to fire on managed
643 forest land and disordered logging⁷. Degradation activity data were available at INPE's **DETER**
644 **Program**⁸. Additional information related to forest degradation data is provided in section
645 8.2.

646

Box 3 – Brazilian main monitoring programs relevant to this submission

The activity data related to deforestation and forest degradation (deforestation and forest degradation areas) used in this submission for all Brazilian biomes derive from the **Amazon and Other Biomes Monitoring Program (PAMZ+,** for the acronym in Portuguese) developed by the Earth Observation and Geoinformatics Division (DIOTG, for the acronym in Portuguese) at the Amazon Space Coordination (COEAM, for the acronym in Portuguese)

⁷ Is worth to recall that in previous submissions Brazil have presented information regarding degradation, including " preliminary thoughts" developed by the GTT-MRV (refer to Annex III of " Brazil's submission of a Forest Reference Emission Level (FREL) for reducing emissions from deforestation in the Amazonia biome for REDD+ results-based payments under the UNFCCC from 2016 to 2020", available at: https://redd.unfccc.int/files/frelc_modifiedversion_correction2019.pdf). The "definition" presented for the purpose of this submissions, have taken into consideration previous information presented, as well as, progress made in INPES' monitoring system (i.e., DETER), in order to implement a pragmatic approach to allow the GHG emissions estimation initially for the Amazon biome. Brazil recognize that further consideration is required, in particular to identify and quantify GHG emissions from other degradation drivers in all Brazilian biomes.

⁸ More information is available (in Portuguese) at:

<http://www.obt.inpe.br/OBT/assuntos/programas/amazonia/deter/deter> (Accessed November 9, 2022)

at the National Institute for Space Research (INPE). PAMZ+ has three operational systems to monitor land use and land cover and corresponding changes through satellite images with different temporal and spatial resolutions:

1. **Satellite Monitoring Program of the Brazilian Amazon Forest (PRODES):** since 1988, PRODES monitors the advance of deforestation in the Legal Amazon, being considered the most important tropical forest monitoring program in the world. Currently, the program was expanded and systematically monitors the annual loss of primary vegetation in all the Brazilian biomes. PRODES uses Landsat-like images (NASA/USGS), called “Landsat class” images, which ranges in spatial resolution from 20-30 meters and have at least three available spectral bands (green, red, and infra-red) within the electromagnetic spectrum. PRODES currently uses images from Landsat-8, SENTINEL-2 (European Union), and CBERS-4/4A (INPE/CRESDA, Brazil/China). In forestlands, PRODES identifies polygons of deforestation caused by clear-cut and due to forest progressive degradation. In other phytophysionomies, such as grasslands and savanna-like biomes, PRODES identify only polygons of complete removal of natural vegetation. Specialists map these polygons through visual photointerpretation using the TerraAmazon software. PRODES is an incremental system and identifies deforestation polygons which area is greater than 1 ha. To improve PAMZ+ data dissemination, INPE has developed an online portal (TerraBrasilis - <http://terrabrasilis.dpi.inpe.br>) that aggregates PRODES and DETER data.
2. **Near Real-Time Deforestation Detection System (DETER):** DETER, launched in 2004, is an surveillance support system that quickly maps deforested and degraded areas within forest formations in the Brazilian Legal Amazonia. Since 2015, DETER uses images from the WFI sensor onboarding CBERS-4, CBERS-4A/INPE, and Amazônia-1/INPE satellites (56-64 meters of spatial resolution). Photointerpreters map deforestation and forest degradation using color composites satellite images in addition to soil and shadow fraction images generated through Linear Spectral Mixture Models (LSMM), which highlight, respectively, image features related to selective logging and burning scars. Forest cover patterns identification in images are based on five main elements: tonality, color, form, texture, and context. Alerts from DETER are divided into two groups: the first refers to deforestation classified as either: (a) deforestation with exposed soil; (b) deforestation with vegetation; and (c) mining (Figure 4.2); the second group embraces degradation alerts classified as either: (a) degradation; (b) selective geometric logging; (c) selective logging; and (d) forest fire scar. DETER identifies polygons which area is greater than 3 ha.
3. **Land Use and Occupation Mapping System Project (TerraClass):** TerraClass project was launched in 2010, firstly in the Legal Brazilian Amazon and since 2020 in the Cerrado biome, with the aim of qualifying deforestation identified by PRODES project. Through visual interpretation of color composites and application of remote sensing techniques (such as Linear Spectral Mixture Models, segmentation, cloud detection and threshold slicing) to Landsat satellite images (30 m of spatial resolution), TerraClass classifies areas identified as deforestation into the following thematic classes: primary forest, secondary forest, silviculture, cultivated pasture

on shrubland, cultivated pasture on herbaceous land, perennial agricultural crop, semi-perennial agricultural crop, temporary agricultural crop, mining, urban areas, 'others', not observed area, current year deforestation, non-forest vegetation, and hydrography within the Brazilian Legal Amazon. In the Cerrado, deforestation is qualified as primary forest, secondary forest, silviculture, cultivated pasture, perennial agricultural crop, semi-perennial agricultural crop, one cycle temporary agricultural crop, over one cycle temporary agricultural crop, mining, urban areas, other edified areas, others, not observed, annual deforestation, and hydrography. TerraClass has as minimum mapping area of 4 ha for both Amazon and Cerrado. The project aims to generate land use and land cover data every two years. Currently, TerraClass data are available for 2004, 2008, 2010, 2012, and 2014 for the Brazilian Legal Amazon and 2018 for the Cerrado Biome.

The systems are complementary and are designed to meet different objectives.

3.5.1. Descriptions of changes to previously submitted forest reference emission levels and/or forest reference

Paragraphs 11 and 10 of decision 12/CP.17, respectively, point out that a subnational FREL may be developed as an interim measure during the transition to a national FREL; and that a stepwise approach to a national FREL may be appropriate, allowing the Parties to improve submissions over time by incorporating more up-to-date data, refining methodologies and, where appropriate, including additional pools and activities.

The main changes included in this submission and that are detailed in the sections to follow are:

1. Inclusion of all 6 Brazilian biomes;
2. Inclusion of forest degradation in the Amazon biome;
3. Estimation of net emissions from deforestation in the Amazon and Cerrado biomes;
4. Change in the biome's geographical boundaries using the most recent official data (IBGE, 2019);
5. Use of a minimum mapping area (MMU) of 1 hectare for the identification of deforestation polygons in all Brazilian biomes;
6. Reference period calculated using 5 years; and
7. Inclusion of uncertainties analysis.

The status of the "areas for future improvements" identified in the reports of the technical assessment carried out in previous Brazilian submissions are explained in section 8.9.

3.5.2. Potential future improvements

In previous FREL submissions Brazil have presented subnational FRELs for the Amazon and Cerrado biomes⁹. In this submission Brazil have incorporated more up-to-date data and refined methodologies to submit a national FREL, that cover 100% of its national territory. The FREL has been developed based on the average net GHG emission estimates for Amazon and Cerrado biomes and the average gross GHG emissions for the remaining four Brazilian biomes considering the five annual periods (from 2016-2017 to 2020-2021).

Nevertheless, is important to clarify that due to its large territorial extension and forest diversity within the different biomes, it was not possible yet to include in this submission all REDD+ activities, and to estimate emissions and removals for all GHGs and all carbon pools for all biomes.

In this submission, Brazil has included uncertainty estimates for all data input and all emissions and removals results. However, it was not possible to use country specific uncertainty values for many of the emission and removal factors and other parameters. For these, uncertainty values derived from the 2006 IPCC Guidelines default values have been used. Plans for future submissions include the development of country specific uncertainty estimates for carbon content for all carbon pools in all biomes and phytophysiognomies, as already done for the Amazon biome, and country specific uncertainty estimates for the parameters used in the natural regeneration and degradation calculations (e.g. biomass growth yearly rate, combustion factor).

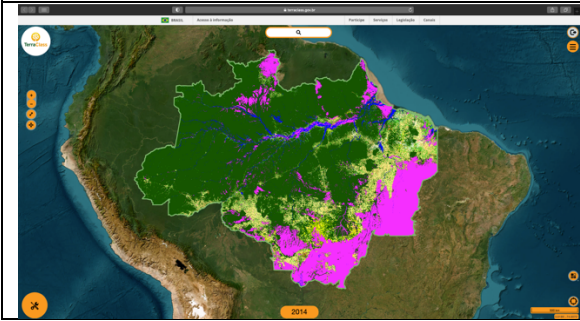

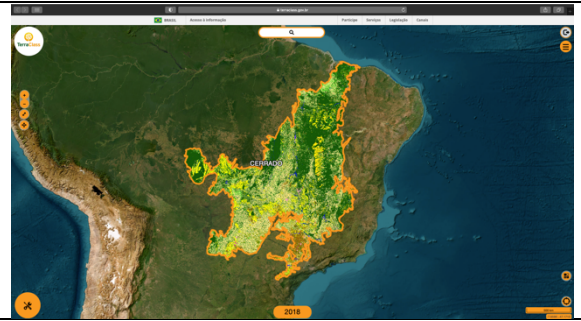

In the following boxes a justification for the non-inclusion of the soil carbon pool in the construction of the national FREL (**Box 8**) is provided, as well as an explanation of the challenges faced to estimate emissions from forest degradation from fire in managed land in the Cerrado biome (**Box 5**); from fire in forest managed land in other biomes (**Box 6**); degradation from regular selective logging (**Box 7**); and removals from natural regeneration (**Box 4**) for all biomes except Amazonia and Cerrado.

⁹ Available at: <https://redd.unfccc.int/submissions.html?country=bra>

Box 4 – Removals

Carbon removals from the annual increase in biomass from natural regeneration of areas previously deforested (**secondary vegetation growth**), have been estimated for the Amazon and Cerrado biomes, using data from **TerraClass Project**.

TerraClass Project was initiated in 2010 in the Amazon biome with the aim to “qualify” the deforestation in the Amazon region; and to offer subsidies for the development of governmental actions related to the development of sustainable agricultural production, preservation of national biodiversity and maintenance of environmental services quality. In 2015, the Project was expanded to include the Cerrado biome. Nowadays, maps with the identification of secondary vegetation are available in TerraClass only for specific years, as indicated below:

| Amazon biome ¹⁰ | Cerrado biome ¹¹ |
|--|---|
| 2004, 2008, 2010, 2012, 2014 and 2020 (in validation) | 2018 and 2020 (in validation) |
|  |  |

Source: TerraClass

The fact that TerraClass does not provide a complete time-series for both Amazon and Cerrado biomes did not allow the estimation of removals for each single year of the reference level period. Hence, in the construction of the national FREL, a linear annual growth was assumed for all years of the reference period, based on the average carbon removals (tonne of C per hectare per year) in those areas of secondary vegetation identified for each biome, as presented in the 4th National GHG Inventory (additional information in section “Estimation of Brazil’s national FREL”).

Pending on additional resources for TerraClass Project, Brazil plans to estimate specific annual removals from secondary vegetation for each single year in future submissions.

Box 5 – Degradation due to fire in managed forest land in the Cerrado

INPE's **"Queimadas" Program**¹² uses images of low (1km) from MODIS program to monitor "fire spots" in the entire country. For each "fire spot" identified, a 1km² buffer area is created to provide an approximate estimate of the "total burned area". This estimate does not correspond to the "burned area scar" since not necessarily all the vegetation included in the buffer zone might have been affected by the fire.

Presently, on an experimental basis, the "Queimadas Program" is using 30m spatial resolution data to monitor both "fire spots" and "burned area scars" in the Cerrado biome based on data from Thematic Mapper (TM) and Operational Land Imager (OLI) onboard satellites LANDSAT 5 and LANDSAT 8, assuming a maximum of 10% cloud cover. The "burned area scars" have been identified using a semi-automatic algorithm and the multi-temporal change between images (Melchiori, 2014). The results of the local evaluation depend not only on the classifier algorithm, but also on the data used as a reference. Therefore, it is essential that reference data are reliable and cover the same study period. There is no guarantee that this experimental initiative using medium spatial resolution will have continuity. Besides that, only results for years 2018 and 2019 are available.

As an example of the experimental initiative just mentioned, this box provides estimates of GHG emissions using "burned area scars" generated by INPE's Queimada Monitoring Group.

| Period | Emissions from forest degradation due to fire in managed forest land in the Cerrado biome (tonnes CO ₂ eq) |
|------------|---|
| 2017-2018 | 29,718,968 |
| 2018--2019 | 60,925,571 |

Source: own elaboration

For the Amazon biome, the "burned area scars" derive from visual interpretation of DETER data that allows then to estimate emissions from forest degradation due to fire. Unfortunately, the DETER system has not been developed for the Cerrado biome preventing the same approach used for Amazonia to extend to the Cerrado.

The situation regarding the identification of forest degradation by fires is then the following: (1) "burned area scars", instrumental to estimate GHG emissions from fire, is not available through the national coverage 1km x 1km spatial resolution data provided by MODIS; and (2) "burned area scars" available through the ongoing experimental initiative

¹² More information (in Portuguese) is available at: <https://queimadas.dgi.inpe.br/queimadas/aq1km/> (Accessed November 9, 2022)

at INPE might not have continuity in the short/medium term. Considering these and the possibility that “burned area scars” data might not be available for future results, impacting the consistency between the national FREL and the results in the BUR Technical Annex, it was decided not to include GHG emissions from forest degradation due to fire in managed forest land occurring in the Cerrado biome.

Pending on additional resources for INPE's “Queimadas” Program, Brazil plans to include these emissions in future submissions.

709

710

**Box 6 – Degradation due to fire in managed forest land in other biomes
(and non-CO₂ emissions)**

According the INPE's "Queimadas" Program data the burned areas in each biome and each year of the reference period are provided in the table below. The table also includes the relative contribution (%) of each biome to the total annual area burned.

| Year / Biome burned area (km ²) | Amazon | Caatinga | Cerrado | Atlantic Forest | Pampa | Pantanal | Total (annual) |
|---|-----------------|-----------------|------------------|--------------------|---------------|-----------------|-------------------|
| 2016 | 65,139 (23%) | 33,309 (12%) | 151,142 (54%) | 18,608 (7%) | 1,527 (1%) | 11,245 (4%) | 280,970 |
| 2017 | 91,240 (30%) | 29,704 (10%) | 158,352 (52%) | 16,260 (5%) | 1,608 (1%) | 9,829 (3%) | 306,993 |
| 2018 | 43,171 (25%) | 25,432 (15%) | 85,374 (50%) | 13,295 (8%) | 615 (0%) | 3,094 (3%) | 170,981 |
| 2019 | 72,450 (23%) | 55,184 (17%) | 148,211 (47%) | 19,405 (6%) | 1,396 (0%) | 20,833 (7%) | 317,479 |
| 2020 | 77,396 (25%) | 30,453 (10%) | 139,644 (45%) | 17,928 (6%) | 6,113 (2%) | 40,606 (13%) | 312,140 |
| 2021 | 45,585 (17%) | 49,869 (18%) | 137,631 (50%) | 20,876 (8%) | 1,228 (0%) | 19,219 (7%) | 274,408 |

Source: <https://queimadas.dgi.inpe.br/queimadas/aq1km/>

The absolute values of the burned areas were obtained using 1km x 1km spatial resolution data but, as mentioned before, they do not necessarily represent the "burned area scars". From the table it is clear that the biome most affected by fires in the Cerrado biome (annual average of 49.5%), followed by the Amazonia biome (annual average of 24%); for the Caatinga biome, the annual average is 13.6%, whereas for Atlantic Forest, Pampa and Pantanal biomes, the annual averages are 6.7%, 0.5% and 6%, respectively. Amazonia and the Cerrado biomes comprise, on average, almost 75% of the area burned in the reference period.

Besides the areas burned in Atlantic Forest, Pampa and Pantanal being much smaller than those in Amazonia and Cerrado, for these biomes and for the Caatinga, the total carbon stock is also comparatively smaller and the potential impact on the GHG emissions is not expected to be large. This is one of the justifications of why forest degradation due to fire is not included in the estimates of the average annual emissions in these biomes.

A graphical representation of the data in the table is presented in the figure below.

Figure 12 – Burned area per biome

Source: “Queimadas” Program

In addition, is worth to mentioning that not all fires occur in forest managed land and not all fires generate “burned area scars”, as already indicated. The following figures provide examples of forest fires in dense forest areas.

Figure 13 – Examples of forest fires in dense forest areas

Source: INPE

From the above figures, it can be seen that fires affect mainly the lower portions of the canopy but depending on its intensity, it may also propagate to higher levels. When the

higher levels of the canopy are not reached, the area affected by the fire will hardly leave a scar that can be identifiable in orbital images.

Therefore, this submission does not include GHG emissions from degradation due to fire in managed forest land expect for the Amazon biome.

Pending on additional resources for the INPE's "Queimadas" Program, Brazil plans to include these emissions in future submissions (if demonstrated to be significant).

Box 7 – Decrease in carbon stocks due to orderly logging

DETER System maps changes in forest cover due to timber extraction considering “disordered selective cutting” (Type 1) and “orderly selective cutting” (Type 2).

In the estimates of emissions from forest degradation, the changes in carbon stocks decrease from “orderly selective cutting” (regular logging) were not included in the construction of this FREL, since the orderly pattern it is associated with activities under sustainable management plans.

The **National System of Forest Products Origin Control (SINAFLO**R, for the acronym in Portuguese)¹³ is in the process of including in its database all approved sustainable management plans (including their geographic coordinates). In the absence of this information, it was not possible to identify among which of the “orderly selective cutting” areas were associated with approved sustainable management activities or not. In this submission it was assumed that all “orderly selective cutting” were associated with approved sustainable management plans, and hence not considered as forest degradation. Brazil plans to revise such classification, in future submissions, once the SINAFLO R database is updated.

Nevertheless, decreases in carbon stocks in areas associated with “orderly selective cutting” (regular logging) were considered in cases where these areas were subject subsequently to other activities (forest fires or deforestation).

It is worth noting that the shapefiles, used in this submission (see “Activity data vectorial files (shapefiles)”) contain data on changes in forest cover due to “orderly selective cutting” (regular logging); but only the data related to “disordered selective cutting” (irregular logging) have been used to estimate forest degradation emissions, due to the rationale explained above.

¹³ More information is available (in Portuguese) at: <http://www.ibama.gov.br/sinaflor> (Accessed on November 9, 2022)

716

Box 8 – Soil carbon

Soil Organic Carbon (SOC) was not included in the construction of the national FREL based on the following rationale:

- (1) Normally, the largest changes in SOC result from the conversion of forest land to other land-use categories (e.g., Cropland, Grassland). In this submission, the identification of the land-use category post deforestation was not made, and hence there would be high uncertainties associated with the SOC changes estimates.
- (2) The 4th National Inventory indicates that SOC contributed only with 2.5% to the total net emissions in the LULUCF sector during the period 2010-2016 (Brazil, 2020). The reference report of the 4th Inventory provides details about the methodology used to estimate SOC emissions, following the IPCC 2006 Guidelines and presents for each type of land use/land cover conversion the change factors used.

Considering the low contribution of SOC to the total LULUCF emissions and considering that this submission is national, it was decided that SOC would not have a significant contribution to the national FREL and hence was not considered.

717

718

3.6. Amazon biome

3.6.1. Activity data

As explained in section “Pools, gases, and activities included in Brazil’s national FREL”, the activity data used for the Amazon biome (deforestation areas, degradation areas – fire and selective logging and natural regeneration areas) were obtained from PRODES, DETER and TerraClass, respectively. The following figures present the distribution of the native forest in the Amazon biome in 2016 (first year of the reference level period) and 2021 (final year of the reference level period).

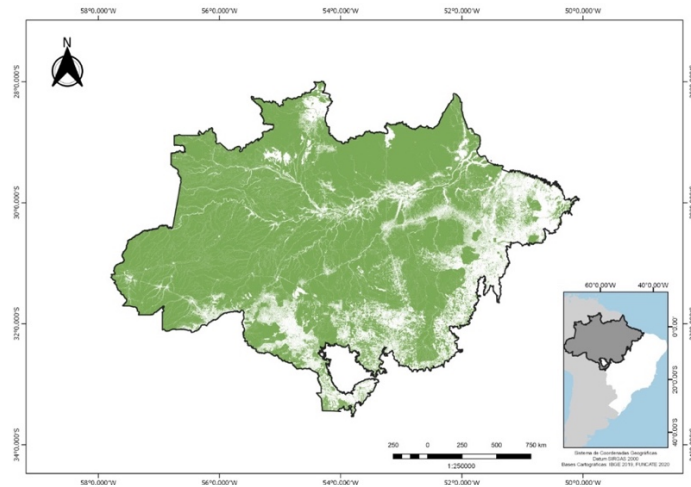

Figure 14 – Native forest (in green) distribution in the Amazon biome in 2016

Source: PRODES

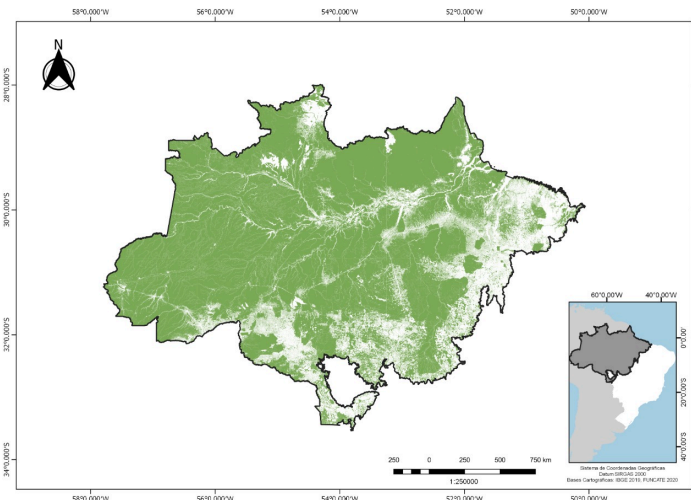

Figure 15 – Native forest (in green) distribution in the Amazon biome in 2021

Source: PRODES

739

740 3.6.2. Emission factors

741

742 Thirty-six (36) forest phytophysognomies are present in the vegetation map of the Amazon
 743 biome, the most abundant ones being *Submontane Dense Ombrophilous Forest* (Ds) and
 744 *Lowland Dense Ombrophilous Forest* (Db). **Table 4** presents the average, minimum and
 745 maximum values of carbon stocks for each carbon pool considered per forest
 746 phytophysognomies. For each type of forest phytophysognomies, the total stock
 747 corresponds to the sum of the individual carbon stocks for the four carbon pools included:
 748 above ground biomass (AGB), below ground biomass (BGB), dead wood (DW) and litter (LI).

OBS: Is worth to note that the values presented in table 23 of the 4th National GHG Inventory (Brazil, 2020) differ from the values presented in this table, even if both the inventory and the FREL use EBA values. The values in this table were extracted directly from the EBA raster file considering each deforestation polygons and hence, they are values that represent "activity data level". In the 4th National GHG Inventory, table 23 values represent the "biome level".

Other emission factors and parameter used to estimate GHG emissions and removals in the Amazon biome are presented in the following table.

Table 5 – Other emission factors and parameters used in the Amazon biome

3.7. Cerrado biome

3.7.1. Activity data

As explained in section “Pools, gases, and activities included in Brazil’s national FREL”, activity data (deforestation areas) for the Cerrado biome were obtained from PRODES. The following figures present the native forest distribution in the Cerrado biome in 2016 (first year of the reference level period) and 2021 (final year of the reference level period).

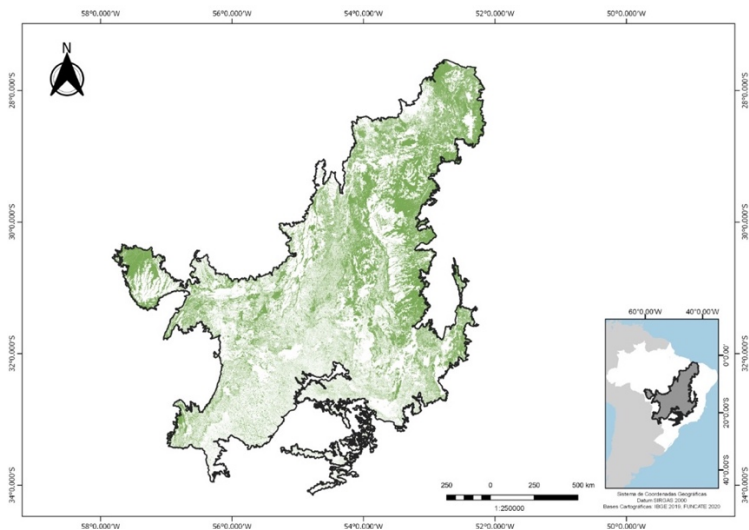

Figure 16 – Native forest (in green) distribution in the Cerrado biome in 2016

788

789 3.7.2. Emission factors

790

791 Thirty-three (33) forest phytophysognomies are present in the vegetation map of the Cerrado
 792 biome, the most abundant one being the Wooded Savanna (Sa). **Table 6** presents the forest
 793 phytophysognomies considered in the Cerrado biome, for the construction of the FREL, and
 794 the respective carbon stocks for each carbon pool. For each type of forest
 795 phytophysognomies, the total stock corresponds to the sum of the individual stocks of the
 796 four carbon pools included: above ground biomass (AGB), below ground biomass (BGB), dead
 797 wood (DW) and litter (LI).

3.10. Pampa biome

3.10.1. Activity data

As explained in section “Pools, gases, and activities included in Brazil’s national FREL”, activity data for the Pampa biome were obtained from PRODES. The following figures present the native forest distribution in the Pampa biome in 2016 (first year of the reference level period) and 2021 (final year of the reference level period).

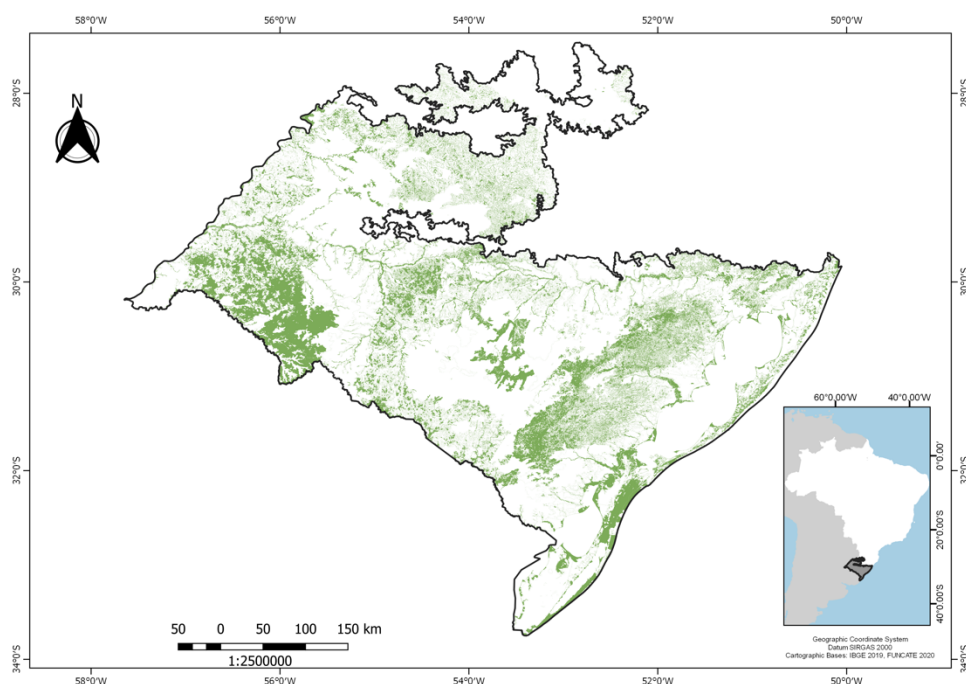

Figure 22 – Native forest (in green) distribution in the Pampa biome in 2016

3.10.2. Emission factors

Twenty-eight (28) forest phytophysiognomies are present in the vegetation map of the Pampa biome, the most abundant one being Steppes (E). **Table 10** present the forest phytophysiognomies considered in the Pampa biome, for the construction of the FREL, and the respective carbon stocks for each carbon pool considered. For each type of forest phytophysiognomies, the total stock corresponds to the sum of the individual stocks of the four carbon pools included: above ground biomass (AGB), below ground biomass (BGB), dead wood (DW) and litter (LI).

3.11.2. Emission factors

Fifteen (15) forest phytophysiological types are present in the vegetation map of the Pantanal biome, the most abundant ones being Wooded Savanna (Sa) and Forested Savanna (Sd). **Table 11** presents the forest phytophysiological types considered in the Pantanal biome, for the construction of the FREL, and the respective carbon stocks for each carbon pool. For each type of forest phytophysiological type, the total stock corresponds to the sum of the individual stocks of the four carbon pools included: above ground biomass (AGB), below ground biomass (BGB), dead wood (DW) and litter (LI).

4. Methodological information used in the construction of Brazil's national FREL

4.1. The role of the Working Group of Technical Experts on REDD+ for MRV

On April 4th, 2022, the Brazilian Ministry of the Environment (MMA, for the acronym in Portuguese) created the **Working Group of Technical Experts on REDD+ for MRV** (GTT MRV REDD+, for the acronym in Portuguese) through Ordinance No. 7/2022. This group is composed of experts in the areas of climate change and forestry from renowned Brazilian institutions.

The GTT MRV REDD+ has provided important inputs for the development of this FREL, including advise on the definition of deforestation and degradation, the forest physiognomies to be considered, the carbon pools and GHG to be included¹⁴.

4.2. Estimation of Brazil's national FREL

The methodologies used to estimate greenhouse gas (GHG) emissions resulting from deforestation and forest degradation, and carbon removals are based on the 2006 IPCC Guidelines (IPCC, 2006).

Overall, estimates of GHG emissions (measured in tonnes of carbon dioxide equivalent (tCO₂ equivalent) result from the multiplication of activity data and emission factors. Emissions were calculated chronologically to allow the gradual reduction of carbon stocks in the appropriate pools over time, when appropriate. This approach ensures that emissions are not overestimated, since the carbon stock available at time *t* is the remaining stock at the time *t*-1 (**Figure 26**).

¹⁴ The GTT MRV REDD+ proceedings are registered in Portuguese and made publicly available on the website of the MMA through the following link: <http://redd.mma.gov.br/pt/reunioes>

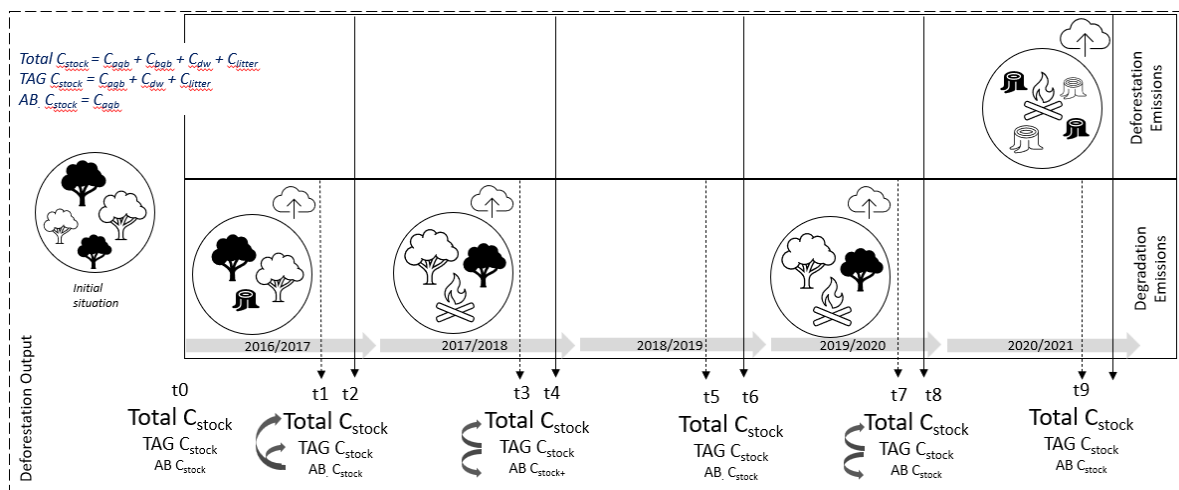

Figure 26 – Methodological approach to estimate GHG emissions from deforestation and forest degradation

Source: own elaboration

Considering that different REDD+ activities impact different carbon pools, the following terms were used in the calculation spreadsheets:

- Total carbon stock (Total C_{stock}):** sum of the four carbon pools considered – above ground biomass, below ground biomass, dead wood, and litter, relevant to the estimation of emissions associated with deforestation:

$$Total\ C_{stock} = C_{AGB} + C_{BGB} + C_{DW} + C_{LI}$$

- Aerial carbon stock (TAG C_{stock}):** sum of the aerial carbon pools – above ground biomass, dead wood and litter, relevant to the estimation of emissions related to fire in managed forest land:

$$TAG\ C_{stock} = C_{AGB} + C_{DW} + C_{LI}$$

- Carbon stock in above ground biomass (AGB C_{stock}):** it concerns only above ground biomass, relevant to the estimation of emissions associated with disordered logging:

$$AGB\ C_{stock} = C_{AGB}$$

The calculations can be divided into three phases:

PHASE 1 - Spatial data layers (maps) were assessed through GIS tools to check gaps, and topology, among others. Problems encountered at this stage and how they were corrected are described in "Quality control and quality assurance procedures". Since

the data volume is very large, the results of this phase were exported as three different outputs (i.e., three worksheets for subsequent calculations), as detailed below:

DEFORESTATION OUTPUT: Contains all deforested areas from 2016-2017 to 2020-2021 and corresponding trajectories, i.e. forest areas that were first subject to degradation and were subsequently deforested are included in these files and tables. In the case of the Amazon biome, these results were subdivided into two parts: i) deforested areas with minimum mapping unit (MMU) between 1 ha and 6.25 ha; and ii) deforested areas of 6.25 ha and above. This subdivision was necessary since the deforestation data produced annually by INPE for the Legal Amazon region (PRODES) uses MMU of 6.25 ha or above, to ensure consistency along the timeseries since 1988

DEGRADATION OUTPUT: Contains all forest areas in managed land subject to degradation in the Amazon biome and that are not converted to deforestation until the last annual period of the reference period (2020-2021)

SECONDARY VEGETATION OUTPUT: Contains all areas under natural forest regeneration in previously deforested areas for years 2014 and 2020 (for the Amazon biome) and 2018 and 2020 (for the Cerrado biome)

PHASE 2 – in this phase, GHG emissions calculations were performed chronologically for forest degradation and deforestation. This implies that the carbon losses from the initial carbon stock in 2016 were accounted for as each REDD+ activity occurred and the carbon stocks were progressively updated so as to avoid double counting between deforestation and degradation in the case of the Amazon biome. In other words, the process and sequence of degradation was considered for the purposes of calculating emissions in subsequent deforestation (for more details refer to section 8.4). This approach was not applied for removals by secondary vegetation, as detailed below. The calculations and results of this phase were also subdivided according to three output components:

DEFORESTATION OUTPUT: Contains GHG emissions from deforestation. The estimates of emissions from deforestation considered total carbon stock (sum of above ground in the above ground biomass)

DEGRADATION OUTPUT: Contains GHG emissions from forest degradation for the Amazon biome. Emissions from degradation by fire considered only the aerial carbon stock (sum of carbon stock in above ground biomass, dead wood and litter). The estimates of emissions from degradation due to disordered logging considered only the carbon stock in the above ground biomass

SECONDARY VEGETATION OUTPUT: Contains removal estimates due to biomass growth in secondary vegetation areas. Due to the lack of annual data, the annual average of carbon removals were applied to the entire period from 2016-2017 to 2020-2021

PHASE 3 – During this phase the results and final balance of emissions and removals were estimated and the net GHG emissions for the Amazon and Cerrado biomes produced. For the Caatinga, Atlantic Forest, Pampa and Pantanal biomes, only gross GHG emissions were estimated.

Detailed descriptions of the application of the above approaches are available in:

- “Detail description for estimating GHG emissions/removals in the Amazon biome”;
- “Detailed description for estimating GHG emissions/removals in the Cerrado biome”;
- and
- "Detail description for estimating GHG emissions/removals in the Atlantic Forest, Caatinga, Pampa and Pantanal biomes".

4.3. Equations used in the construction of Brazil’s national FREL

Emission and removal estimate for the national FREL are based on the 2006 IPCC gain-loss method (IPCC, 2006). The following equations are used, taking into account the REDD+ activities and the non-CO₂ gases considered for each biome, as indicated in **Table 3**. Detailed information related to the estimation in each biome are described in the section “Estimation of Brazil’s national FREL”. Equation 1 is an adaptation of equation 2.3 in the 2006 IPCC Guidelines:

$$\Delta C_B = \Delta C_{AGB} + \Delta C_{BGB} + \Delta C_{DW} + \Delta C_{LI} \quad \text{Equation 1}$$

Where:

- ΔC_B = carbon stock change
- ΔC_{AGB} = above-ground biomass stock change
- ΔC_{BGB} = below-ground stock change
- ΔC_{DW} = dead-wood stock change
- ΔC_{LI} = litter stock change

4.3.1. Gross deforestation emissions

For each deforestation polygon i , identified at each annual period of the reference level period, the associated CO₂ emission is estimated as the product of its area (hectares) and the total carbon stocks (sum of the carbon stocks in the carbon pools considered), multiplied by 44/12 to convert tonnes of carbon in tonnes of carbon dioxide. Erro! Fonte de referência não encontrada.

$$GE_{b,t,f,p} = A_{b,t,f,p} * (Ca_{b,t,f,p} + Cb_{b,t,f,p} + Cd_{b,t,f,p} + Cl_{b,t,f,p}) * 44/12 \quad \text{Equation 2}$$

Where:

- $GE_{b,t,f,p}$ = CO₂ emissions associated with deforestation in the polygon p , under phytophysiological nomies f of the biome b , at the annual period t ; (tonnes)
- $A_{b,t,f,p}$ = area of deforestation polygon p , under phytophysiological nomies f of the biome b , at the annual period t ; (ha)
- $Ca_{b,t,f,p}$ = carbon stock in above ground biomass in polygon p under phytophysiological nomies f of biome b at the annual period t (tC)
- $Cb_{b,t,f,p}$ = carbon stock in below ground biomass in polygon p under phytophysiological nomies f of biome b at the annual period t (tC)
- $Cd_{b,t,f,p}$ = carbon stock in deadwood in polygon p under phytophysiological nomies f of biome b at the annual period t (tC)
- $Cl_{b,t,f,p}$ = carbon stock in litter in polygon p under phytophysiological nomies f of biome b at the annual period t (tC)
- $44/12$ = conversion factor from C to CO₂; (dimensionless)

For each biome b and annual period t , the total gross CO₂ emissions from deforestation is estimated as the sum of the CO₂ emissions from all deforested polygons identified in that period, as expressed in Equation 3:

$$GE_{bt} = \sum_{p=1}^{P_{b,t}} GE_{b,t,p} \quad \text{Equation 3}$$

Where:

- GE_t = total CO₂ emissions for period t in biome b ; tonnes of CO₂
- GE_i = CO₂ emissions associated with deforested polygon p ; tonnes of CO₂
- $P_{b,t}$ = number of deforested polygons identified in the period t and biome b ; dimensionless

4.3.2. Gross emissions due degradation from fire

To estimate emissions from forest degradation due to fire, the generic equation 2.14 in the 2006 IPCC GLs, was used¹⁵, as reproduced below in equation 4:

$$L_{disturbance} = \{A_{disturbance} \times B_w \times (1 + R) \times CF \times fd\} \quad \text{Equation 4}$$

Where:

- $A_{disturbance}$ = area affected by the disturbance (hectares)
- B_w = average above-ground biomass of land areas affected by disturbances, tonnes d.m. ha⁻¹

¹⁵ Equation 2.14 of Chapter 2 (Generic Methodologies Applicable to Multiple Land-Use Categories) of Volume 4 (Agriculture, Forestry and Other Land Use) of 2006 IPCC Guidelines for National Greenhouse Gas Inventories. Available at: https://www.ipcc-nggip.iges.or.jp/public/2006gl/pdf/4_Volume4/V4_02_Ch2_Generic.pdf

- **R** = ratio of below-ground biomass to above-ground biomass, in tonne d.m. below-ground biomass (tonne d.m. above-ground biomass)⁻¹. R has been set to zero, assuming no changes of below-ground biomass
- **CF** = carbon fraction of dry matter, tonne C (tonnes d.m.)⁻¹
- **fd** = fraction of biomass lost in disturbance

Non-CO₂ emissions are estimated following equation 2.27 in the 2006 IPCC GLs¹⁶, reproduced in equation 5:

$$L_{fire} = A \times M_B \times C_f \times G_{ef} \times 10^{-3} \quad \text{Equation 5}$$

Where:

- **L_{fire}** = amount of GHG emissions from fire of each GHG (CH₄ and N₂O)
- **A** = area burned; hectares
- **M_B** = biomass available; tonnes per hectare
- **C_f** = combustion factor; dimensionless
- **G_{ef}** = emission factor; g/kg of dry matter burned

Each tonne of GHG was converted to tonne of CO₂ equivalent, using the 100-year GWP values from the IPCC 5th Assessment Report¹⁷:

- CH₄ to CO₂ = 28
- N₂O to CO₂ = 265

4.3.3. Gross emissions due to disordered logging degradation

For each identified disordered logging polygon (CS), a trajectory was assessed (i.e., recurrences during the reference period, if any) and a singular above-ground “biomass loss factor” used accordingly - **Table 12**. The percent losses of above ground biomass (ΔCL CS AGB) in table 12 are the same as those in table 30 of Brazil (2020).

Table 12 – Representation of possible disordered logging trajectories (recurrences) and respective above-ground “biomass loss factor”

| Potential trajectory from F-CS | | | | | |
|--------------------------------|--|-----|-----|-----|----------------|
| Initial area | Disordered logging within the reference level period | | | | ΔCL CS AGB (%) |
| F | CS1 | | | | -29% |
| F | CS1 | CS2 | | | -27% |
| F | CS1 | CS2 | CS3 | | -26% |
| F | CS1 | CS2 | CS3 | CS4 | -22% |

¹⁶ Equation 2.27 of IPCC 2006 Chapter 2

¹⁷ Table 8.A.1 available at: https://www.ipcc.ch/site/assets/uploads/2018/02/WG1AR5_Chapter08_FINAL.pdf

Source: Table 30 (Brazil, 2020)

4.3.4. Removals due to natural forest regeneration in areas previously deforested

For each polygon j identified at year t of the reference period as undergoing natural regeneration, the CO₂ removal was estimated as the product of its area and the mean annual biomass growth, following equation 2.9 of the 2006 IPCC GLs and reproduced in equation 6:

$$GE_{i,j} = \sum_1^{NR} A_{j,t} \times EF \times 44/12 \quad \text{Equation 6}$$

Where:

- $GE_{j,t}$ = annual increase in biomass carbon stocks in natural regeneration polygon j at time t due to biomass growth in areas of natural regeneration; tonnes of CO₂ per year per hectare
- $A_{i,j}$ = area of polygon j under natural forest regeneration (secondary vegetation) at time t ; (hectares)
- EF = mean annual biomass growth; tonnes of C per hectare
- NR = number of natural regeneration polygons identified at time t
- $44/12$ = conversion factor from C to CO₂

4.3.5. Uncertainties equations

Uncertainties associated with GHG emissions were estimated using equations described in volume 1, chapter 3, page 3.28 of 2006 IPCC Guidelines:

COMBINING UNCERTAINTIES – APPROACH 1 – MULTIPLICATION

$$U_{total} = \sqrt{U_1^2 + U_2^2 + \dots + U_n^2} \quad \text{Equation 7}$$

Where:

- U_{total} = the percent uncertainty of the product of the quantities
- U_i = the percent uncertainty associated with each of the quantities

COMBINING UNCERTAINTIES – APPROACH 1 – ADDITION AND SUBTRACTION

$$U_{total} = \frac{\sqrt{(U_1 \cdot x_1)^2 + (U_2 \cdot x_2)^2 + \dots + (U_n \cdot x_n)^2}}{|x_1 + x_2 + \dots + x_n|} \quad \text{Equation 8}$$

1205

1206 Where:

- 1207 • U_{total} = the percent uncertainty of the product of the quantities
- 1208 • X_i and U_i = the added quantities and the percentage uncertainties associated with
- 1209 them, respectively

1210

1211 Applying equations 7 for equation 2, will result in:

$$U_{GEij} = \sqrt{U_{Aij}^2 + U_{EFj}^2} \quad \text{Equation 9}$$

1213

1214 Where:

- 1215 • GE_i = CO₂ emissions due to deforestation of areas under phytophysiognomies I (t)
- 1216 • A_i = Total area deforested under phytophysiognomies I (ha)
- 1217 • C_i = Total carbon content of areas under phytophysiognomies I (tC/ha)
- 1218 • $C_i = Cab_i + Cbb_i + Cdw_i + Cli_i$ as defined in Equation 2

1219

1220 Applying equation 8:

$$U_{C_i} = \frac{\sqrt{(U_{Cab_i} \cdot Cab_i)^2 + (U_{Cbb_i} \cdot Cbb_i)^2 + (U_{Cdw_i} \cdot Cdw_i)^2 + (U_{Cli_i} \cdot Cli_i)^2}}{C_i} \quad \text{Equation 10}$$

1222

1223 The above equations assume that each component is not correlated. This is reasonable in
 1224 relation to activity data (i.e., deforested area) and the total carbon content, but it does not
 1225 always apply in relation to the carbon content for each carbon pool. In the case where the
 1226 carbon content for below-ground biomass, litter and dead wood are estimated based on the
 1227 estimate of the carbon stock in above-ground biomass, the equations should be revised. For
 1228 example, in the case in which all other carbon pools were obtained from aerial biomass,
 1229 equation 11 applies:

1230

$$C_i = Cab_i + Rbb_i \cdot Cab_i + Rdw_i \cdot Cab_i + Rli_i \cdot Cab_i \quad \text{Equation 11}$$

1232

1233 Where:

- 1234 • Rbb_i = Ratio below ground biomass / aboveground biomass for phytophysiognomies I
- 1235 • Rdw_i = Ratio dead wood biomass / above ground biomass for phytophysiognomies I
- 1236 • Rli_i = Ratio litter / above ground biomass for phytophysiognomies i

Applying equations 7 and 8:

$$U_{C_i} = \sqrt{U_{Cab_i}^2 + \frac{\left((Rbb_i * U_{Rbb_i})^2 + (Rdw_i * U_{Rdw_i})^2 + (Rli_i * U_{Rli_i})^2\right)}{(1 + Rbb_i + Rdw_i + Rli_i)^2}} \quad \text{Equation 12}$$

Specific information on how activity data uncertainty (U_{Aij}) and EF uncertainties (U_{EFj}) were estimated can be found in section “Accuracy”.

4.3.6. FREL

The annual emissions were obtained using the following equation, taking into account the REDD+ activities and removals considered in each biome, as indicated in **Table 3**:

$$\text{Gross/Net emissions} = \text{Gross emissions from deforestation} + \text{Gross emissions from forest degradation due to fire} + \text{Gross emissions from degradation due to disordered logging} - \text{Removals from natural forest regeneration (only for Amazon and Cerrado biomes)}$$

Equation 13

Finally, the national FREL was obtained from the sum of the average of gross/net annual emissions in the reference level period:

$$MGE_p = \sum_1^b GE_t \quad \text{Equation 14}$$

Where:

- MGE_p = average gross/net GHG emissions for biome b ; tonnes of CO₂ eq per year
- GE_t = gross/net emission in year t ; tonnes of CO₂ eq
- b = number of biomes

5. Transparent, complete, consistent, and accurate information

In addition to information presented in previous sections, this section follows the guidelines contained in the Annex to decision 12/CP.17¹⁸ on submitting reference levels and IPCC principles of: **Transparency, Accuracy, Completeness and Consistency (TACC principles)**.

5.1. Transparency

For additional information aiming to enhance the transparency of the submission, refer to annexes:

- Additional information related to deforestation activity data;
- Additional information related to forest degradation activity data;
- Additional information related to the areas of natural forest regeneration (secondary vegetation);
- Detail description for estimating GHG emissions/removals in the Amazon biome;
- Detailed description for estimating GHG emissions/removals in the Cerrado biome;
- Detail description for estimating GHG emissions/removals in the Atlantic Forest, Caatinga, Pampa and Pantanal biomes; and
- Detail description for estimating the national FREL.

5.2. Accuracy

The uncertainty associated with CO₂ emissions was estimated based on the uncertainty associated with activity data (e.g., deforested area) and the uncertainty associated with EF (e.g., carbon content in each carbon pool) – for the general equations applied, refer to section “Uncertainties equations”.

5.2.1. Activity data uncertainty

The accuracy of the deforested areas in each biome was estimated using the methodology proposed in (Olofsson, et al., 2014). To determine the accuracy of the interpreter and estimate an uncertainty to be associated with the deforested areas in each annual period from 2016/2017 to 2020/2021, a stratified random sampling was applied according to the two categories adopted (natural forest and deforestation). Reference maps were used for each year from 2016 to 2021.

Sample size, that is, the number of points sampled per stratum, was defined by applying the so-called "Neyman optimal allocation", described by (Cochran, 1977) (Congalton & Green,

¹⁸ Available at: <https://unfccc.int/sites/default/files/resource/docs/2011/cop17/eng/09a02.pdf>

2009) and (Stehman, 2012). First, the total sample size was defined, considering all biomes as a single territory to be sampled:

$$n = \left[\frac{\sum_{i=1}^H W_i * S_i}{s(\hat{O})} \right]^2 \quad \text{Equation 15}$$

Where:

- **n** = total number of samples
- **W_i** = proportion of category *i*
- **S_i** = $\sqrt{U_i * (1 - U_i)}$ = standard deviation of category *i*
- **s(\hat{O})** = standard error expected from sampling
- **U_i** = estimated map accuracy (given by the interpreter)

Sample distribution per category (*n_i*) was estimated using:

$$n_i = n * \frac{(t_{xi})^a * N_i * \sqrt{U_i * (1 - U_i)}}{\sum_{i=1}^H (t_{xi})^a * \sqrt{U_i * (1 - U_i)}} \quad \text{Equation 16}$$

Where:

- **t_{xi}** = **P_i** * **N_i**; where:
 - **P_i** = proportion of category *i* in relation to total population
 - **N_i** = category *i* population (i.e., total number of pixels occupied by category *i*)
- **a=1/2 or 1/3** according to (Särndal, Swensson, & Wretman, 1992)

The following table presents the sample plots numbers per biome and category that were considered for estimating activity data accuracy.

Table 13 – Sample distribution per biome and category

| Biome | Natural vegetation | Deforestation | Total |
|-----------------|--------------------|---------------|-------|
| Amazon | 386 | 208 | 594 |
| Cerrado | 367 | 202 | 569 |
| Caatinga | 449 | 116 | 565 |
| Atlantic forest | 368 | 166 | 534 |
| Pampa | 325 | 417 | 742 |
| Pantanal | 525 | 491 | 1016 |

Source: own calculations

Once the sample size was defined for each biome and category (i.e., natural vegetation and deforestation), the sampled plots were assessed using higher spatial resolution images, allowing for the confirmation or not of the classification.

This step was carried out using a computational system developed by INPE, that allowed the interpreter to simultaneously observe the sampled plot and the high spatial resolution images, complemented by graphical data describing NDVI (Normalized Difference Vegetation Index) dynamics that allowed to identify variations associated with removal, growth or vegetation cover stability at the sample plot over time. The following figure gives an example for each biome of a sample randomly selected, with the supplementary information used to estimate the mapping accuracy: for each sampled point (image at the center) the interpreter had (on the right upside corner) additional high spatial resolution images and the NDVI graph (at the bottom).

Figure 27 – Sample example in each biome for estimating mapping accuracy

Source: INPE

Based on the results of the sample plots process, an error matrix was elaborated for each biome and category – Table 14.

Table 14 – Error matrix for each biome and category

| Biome | Category | Error | | |
|-----------------|--------------------|---------------|--------------------|-------|
| | | Deforestation | Natural vegetation | Total |
| Amazon | Deforestation | 201 | 8 | 209 |
| | Natural vegetation | 7 | 378 | 385 |
| | Total | 208 | 386 | 594 |
| Cerrado | Deforestation | 174 | 20 | 194 |
| | Natural vegetation | 28 | 347 | 375 |
| | Total | 202 | 367 | 569 |
| Caatinga | Deforestation | 108 | 13 | 121 |
| | Natural vegetation | 8 | 436 | 444 |
| | Total | 116 | 449 | 565 |
| Atlantic forest | Deforestation | 159 | 50 | 209 |
| | Natural vegetation | 7 | 318 | 325 |
| | Total | 166 | 368 | 534 |
| Pampa | Deforestation | 408 | 36 | 444 |
| | Natural vegetation | 9 | 289 | 298 |
| | Total | 417 | 325 | 742 |
| Pantanal | Deforestation | 487 | 20 | 507 |
| | Natural vegetation | 4 | 505 | 509 |
| | Total | 491 | 525 | 1016 |

Source: own calculations

From the above matrices it is possible to calculate producer's accuracy (omission) and user's accuracy (inclusion) and the 95% confidence intervals of the classification of the deforested area. The results are presented in following table.

Table 15 – Accuracy matrix for each biome and category

| Biome | Category | User's accuracy % | Deforestation area uncertainty % |
|-----------------|--------------------|-------------------|----------------------------------|
| | | | |
| Amazon | Deforestation | 96.2 | 10.5 |
| | Natural vegetation | 98.2 | |
| Cerrado | Deforestation | 89.7 | 15.8 |
| | Natural vegetation | 92.5 | |
| Caatinga | Deforestation | 89.3 | 26.8 |
| | Natural vegetation | 98.2 | |
| Atlantic forest | Deforestation | 76.1 | 30.6 |
| | Natural vegetation | 97.8 | |
| Pampa | Deforestation | 91.9 | 6.2 |
| | Natural vegetation | 97.0 | |
| Pantanal | Deforestation | 96.1 | 6.9 |
| | Natural vegetation | 99.2 | |

Source: own calculations

5.2.2. Emission factors uncertainty

Above ground biomass uncertainty

For the Amazon biome, uncertainty values for above ground biomass were directly obtained from the EBA project¹⁹, with uncertainty values associated with each pixel in the EBA raster file.

For the other biomes, uncertainty values associated with each phytophysiological vegetation in the biome were used, collected from either bibliographic reference or estimated based on IPCC default values (Table 4.7 in page 4.53 of chapter 4, volume 4 of the 2006 IPCC Guidelines)²⁰. Uncertainty default values were estimated using the predominant, minimum, and maximum limits, assuming a triangular distribution (as suggested by the 2006 IPCC Guidelines). Table 12 shows the values used in table 4.7 and the associated 95% confidence interval. **Erro! Fonte de referência não encontrada.**

Table 16 – Confidence interval and estimated uncertainty for above ground biomass for Cerrado, Atlantic Forest, Caatinga, Pampa and Pantanal biomes

| Domain | Ecological zone | Continent | Above-ground biomass (t d.m. ha ⁻¹) | Uncertainty (%) |
|-----------------|--|-------------------------|--|--------------------|
| Tropical | Tropical rain forest (TRF) | North and South America | 300 (120-400) | -43/+37 |
| | Tropical moist deciduous forest (TMDF) | North and South America | 220 (210-280) | -10/+14 |
| | Tropical dry forest (TDF) | North and South America | 210 (200-410) | -24/+38 |
| | Tropical shrubland (TS) | North and South America | 80 (40-90) | -33/+24 |
| | Tropical mountain systems | North and South America | 60-230 | -46/+46 |

Source: own calculations based on Table 4.7 of 2006 IPCC Guidelines

To estimate phytophysiological uncertainties, each phytophysiological was associated with an ecological zone of **Table 16**.

1396 Source: own calculations

1397 *Other carbon pools uncertainty (below ground biomass, litter, and dead wood)*

1398

1399 Currently, Brazil doesn't have country specific uncertainties values for other carbon pools:
1400 below-ground biomass, litter, and dead wood. Therefore, IPCC default values were used, as
1401 described below.

1402

1403 Below ground biomass

1404 Table 4.4 of the 2006 IPCC Guidelines provides default values for the ratio below ground
1405 biomass/above ground biomass (root-to shoot ratio - R). However, the table does not provide
1406 ranges for all ecological zones. As the ratio "0,20" is used for many phytophysionomies, and
1407 also in order to be conservative, the value 38% was assumed as the uncertainty value for R in
1408 this submission.

1409 **Table 18 – Below ground uncertainty values**

| Ecological zone | Above-ground biomass | R [tonne root d.m. (tonne shoot d.m.) ⁻¹] | Uncertainty (%) |
|---------------------------------|---|---|-----------------|
| Tropical rainforest | | 0.37 | |
| Tropical moist deciduous forest | above-ground biomass <125 tonnes ha ⁻¹ | 0.20 (0.09 - 0.25) | 38 |
| | above-ground biomass >125 tonnes ha ⁻¹ | 0.24 (0.22 - 0.33) | 19 |
| Tropical dry forest | above-ground biomass <20 tonnes ha ⁻¹ | 0.56 (0.28 - 0.68) | 34 |
| | above-ground biomass>20 tonnes ha ⁻¹ | 0.28 (0.27 - 0.28) | 2 |
| Tropical shrubland | | 0.40 | |
| Tropical mountain systems | | 0.27 (0.27 - 0.28) | 2 |

1410

1411 Source: own calculations based on Table 4.4 of 2006 IPCC Guidelines

1412 Dead wood

1413 Table 3.2.2 of the 2003 IPCC GPG LULUCF²¹ has the value 0.11 as the ratio for dead wood and
1414 above ground biomass for "Tropical forest", associating a value of 150% for the uncertainty.
1415 This uncertainty estimate was considered for all cases in which dead wood was estimated
1416 from above ground biomass using an expansion factor.

1417
1418 Litter

1419 Table 3.2.1 of the 2003 IPCC GPG LULUCF²² indicate the value of 2.1 tC/ha (1-3) for litter in
1420 "tropical broadleaf deciduous forests". Based on a triangular distribution, an uncertainty
1421 value of 39% was estimated to be used in all phytophysiognomies. However, in most cases
1422 the carbon content in litter is estimated from above ground biomass carbon content using an
1423 expansion factor. Hence, a value of 22% of uncertainty was associated with the expansion
1424 factor in order to be consistent, on average, with the default value provided in the 2003 IPCC
1425 GPG LULUCF.

1426
1427 *Uncertainty of carbon removals due to natural forest regeneration in areas previously*
1428 *deforested*

1429
1430 The annual removal value is calculated multiplying the area identified as undergoing natural
1431 regeneration by the mean annual biomass growth for secondary forest with past pasture
1432 history (tC/ha year).

1433
1434 The accuracy of the identification of secondary vegetation areas was carried out using the
1435 same methodology described for deforestation. The uncertainties estimated for the
1436 secondary vegetation area in the Amazon and Cerrado biomes were 9.7% and 5.3%,
1437 respectively.

1438
1439 For the mean annual biomass growth, the values used in the 4th National GHG Inventory were
1440 adopted (3.03 tC/ha/year for the Amazon biome and 2.85 tC/ha/year for the Cerrado biome).
1441 It was not possible to obtain uncertainty estimates for these values from the mentioned
1442 references. Typical uncertainty values are described in table 4.9 of the "2006 IPCC Guidelines.
1443 However, this table does not show ranges for all ecological zones. Based on the values in the
1444 table, an uncertainty of 50% (with one significant digit) was adopted for both the Amazon and
1445 the Cerrado biomes. Using the uncertainty propagation equation for the multiplication
1446 presented above, the uncertainty for CO₂ removal was estimated for both Amazon and
1447 Cerrado biomes, equal to 50% (with one significant digit).

1448

²² Available at: https://www.ipcc-nggip.iges.or.jp/public/gpglulucf/gpglulucf_files/Chp3/Chp3_2_Forest_Land.pdf

1449 *Uncertainty of gross emissions due to degradation from fire*

1450

1451 The annual gross emissions due to degradation from fire are estimated applying equations 4
1452 and 5 described above.

1453

1454 The accuracy of the forest areas subject to degradation from fire was carried out using the
1455 same methodology described for deforestation, providing an estimated uncertainty of 19%
1456 for the Amazon biome.

1457

1458 The combustion factor uncertainty was obtained from table 2.6 of the 2006 IPCC Guidelines
1459 for “all primary forests” (0,36 with a 71% uncertainty) consistent with the value used in this
1460 submission (0.368).

1461

1462 The uncertainty of the emission factors for non-CO₂ gases were obtained from table 2.5 of
1463 the 2006 IPCC guidelines (58% for CH₄ and 53% for N₂O).

1464

1465 *Uncertainty of gross emissions due to irregular logging degradation*

1466

1467 For each polygon where irregular logging has been identified, emissions have been estimated
1468 multiplying its area by a biomass loss factor. Logging recurrences are possible for the same
1469 polygon. As shown before, biomass loss factors decrease for recurrent loggings.

1470

1471 The accuracy of the areas subject to irregular logging has been estimated as 20% based on
1472 expert evaluation.

1473

1474 The uncertainty of the biomass loss factors (0.29, 0.27, 0.26 and 0.22 for first, second, third
1475 and fourth recurrences) were considered to be 8% based on expert evaluation.

1476

5.3. Completeness

Complete information, for REDD+ purposes, means the provision of data and information that allows for the reconstruction of the FREL.

Additional information is meant only to enhance clarity and transparency of Brazil's National FREL. Brazil recalls paragraph 2 of Decision 13/CP.19 on guidelines and procedures for the technical assessment of FREL submissions and paragraph 4 of the Annex of the same decision.

In general, all information related to land use environmental monitoring is publicly available at **TerraBrasilis**²³, a geographic data platform developed by INPE and EMBRAPA for the organization, access and use through a web portal of all information produced by its environmental monitoring programs.

The data and information, used in this submission, are available at: <http://redd.mma.gov.br/en/submissions>

5.3.1. Activity data vectorial files (shapefiles)

The following vectorial files containing activity data (i.e., deforestation, degradation and revegetation polygons) and supporting material (i.e., biomes limits, forest physiognomies and managed land areas) are available:

| File name | Content | Source |
|---|--|--|

| 9. Pampa_Net_Emissions_Deforestation | Net emissions from deforestation in the Pampa biome for the period 2016/2017-2020/2021 |
| 10. Pantanal_Net_Emissions_Deforestation | Net emissions from deforestation in the Pantanal biome for the period 2016/2017-2020/2021 |
| 11. National_FREL | Brazil's national FREL for the period 2016/2017-2020/2021 |

5.4. Consistency

5.4.1. Consistency with the latest National Greenhouse Gas Inventory

Paragraph 8 of Decision 12/CP.17 indicates that the reference levels should keep consistency with the country's latest National GHG Inventory. The 4th National GHG Inventory was submitted by Brazil to the UNFCCC in December 2020 and reports net GHG emissions for the LULUCF sector for the period 1990-2016 (Brazil, 2020). Estimates of CO₂ emissions and removals due to land use and land-cover change and Harvested Wood Products, as well as non-CO₂ gases emissions used the 2006 IPCC GLs as a basis for the approaches and methodologies used.

Brazil applied IPCC's definition of consistency (IPCC, 2006) and in the construction of this national FREL used the same methodologies and datasets as those applied to estimates CO₂ and non-CO₂ emissions from the conversion of forest areas (managed and unmanaged) to other land-use categories in the 4th National GHG Inventory.

It should be pointed out, however, that there are differences between the estimates provided in the 4th National GHG Inventory and this FREL submission, due to more updated and accurate data and information that were available at the time of construction of the FREL, in particular:

1. Change in the biome's geographical boundaries; and
2. Use of minimum mapping area (MMU) of 1 hectare for the identification of deforestation polygons in the Amazon biome.

5.4.1.1. Change in biomes' geographical boundaries

IBGE (2019) updated the geographical boundaries of the national biomes which were not available by the time of the development of the 4th National GHG Inventory. The Inventory thus used the boundaries defined in the 2004 IBGE map and that present some differences when compared to the new limits established in 2019 IBGE map, as indicated in **Table 19**.

Table 19 – Comparison between the geographical areas defined in IBGE (2019) and IBGE (2004) and the corresponding biome percent cover in the Brazilian territory

| Biome | Area IBGE (2019) (ha) | Contribution to national area (%) | Area IBGE (2004) / 4 th National GHG Inventory (ha) | Contribution to national area (%) |
|-----------------|--------------------------|---|---|---|
| Amazon | 421.274.200 | 49,5 | 420.877.900 | 49,4 |
| Cerrado | 198.301.700 | 23,3 | 203.582.600 | 23,9 |
| Caatinga | 86.281.800 | 10,1 | 82.784.500 | 9,7 |
| Atlantic forest | 110.741.900 | 13,0 | 111.557.200 | 13,1 |
| Pampa | 19.381.800 | 2,3 | 17.882.600 | 2,1 |
| Pantanal | 15.098.800 | 1,8 | 15.130.300 | 1,8 |
| Total | 851.080.200 | 100 | 851.815.000 | 100 |

OBS: please note that the difference in the geographical area of Brazil from IBGE (2004) (851,815,000 ha) and IBGE (2019) (851,080,200 ha) results from the elimination of areas that are now considered under the so called Coastal Marine System.

Source: IBGE, 2019 and Brazil, 2020

Tables 20 to 25 provide the implication of the of the change in each biome limit on the estimates of the gross GHG emissions from deforestation for Caatinga, Atlantic Forest, Pampa and Pantanal, respectively. For the Amazon, the changes in deforested area and consequent emissions are not significant.

Table 20 – CO₂ emissions from gross deforestation, MMU 6,25ha, based in the former (IBGE, 2004) and in the current (IBGE, 2019) biome limit for Amazon

| Period | 2004 limit | | 2019 limit | | Change in area 2019/2004 | Change in emissions 2019/2004 |
|------------------|-------------------------|---------------------------------------|-------------------------|---------------------------------------|-----------------------------|----------------------------------|
| | Deforestation area (ha) | Gross emission (tCO ₂ /ha) | Deforestation area (ha) | Gross emission (tCO ₂ /ha) | | |
| 2016-2017 | 665,821.49 | 295,787,546.69 | 672,853.72 | 297,211,456.19 | 1.06% | 0.48% |
| 2017-2018 | 696,589.84 | 317,127,695.68 | 692,431.08 | 301,865,997.55 | -0.60% | -4.81% |
| 2018-2019 | 1,064,179.34 | 476,284,434.39 | 1,067,613.09 | 474,543,048.25 | 0.32% | -0.37% |
| 2019-2020 | 1,038,806.82 | 461,063,907.52 | 1,031,985.74 | 443,258,448.53 | -0.66% | -3.86% |
| 2020-2021 | 1,212,868.69 | 556,489,285.94 | 1,215,904.49 | 546,613,958.95 | 0.25% | -1.77% |

Note that the area of the Caatinga biome increased from IBGE (2004) to IBGE (2019) - from 82,784,500 ha to 86,281,800 ha. The deforestation areas in the Caatinga are shown in **Figure 28** – in red, the deforestation areas "lost" to the Cerrado biome due to the new boundaries and in green, the deforestation areas inherited from the Cerrado biome. Quantitatively, the area lost is equal to 77,978.21 ha and the area "gained" is 136,942.27 ha, a difference of 58,964.06 ha.

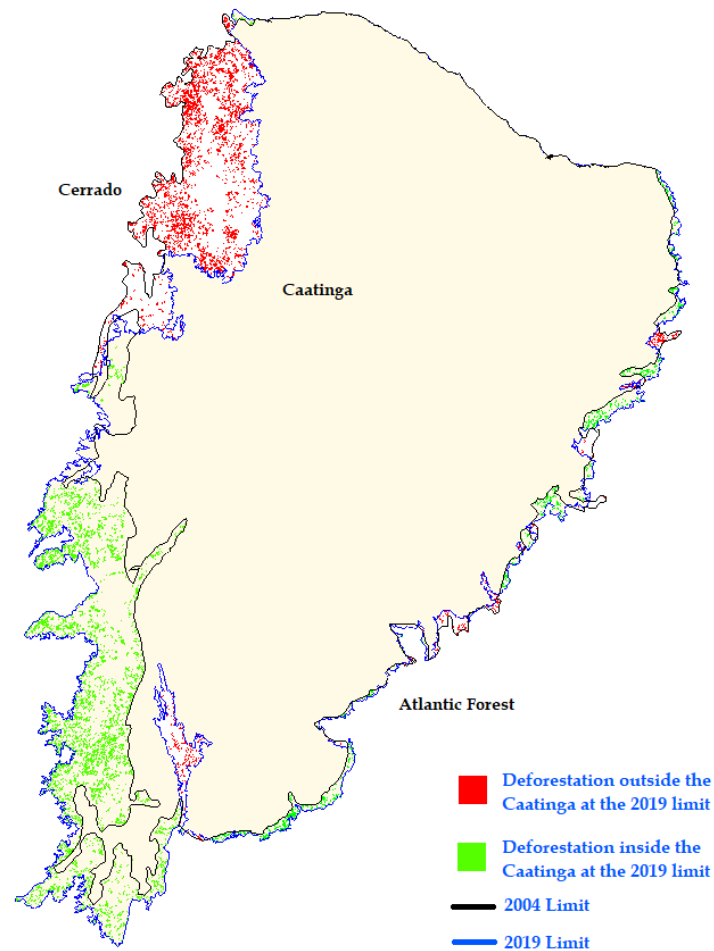

Figure 28 – Deforestation areas in the Caatinga "lost" to the Cerrado biome (in red) and the deforestation areas inherited from the Cerrado biome (in green) due to the new boundaries

The Atlantic Forest boundaries were reduced from IBGE (2004) (122,557,200 ha) to IBGE (2019) (110,741,900 ha) but this change had a very small impact in the average annual emissions, which ranged from –1,79% to 1,14% during the reference period.

Table 24 – CO₂ emissions from gross deforestation based in the former (IBGE, 2004) and in the current (IBGE, 2019) biome limit for Pampa

| Period | 2004 limit | | 2019 limit | | Change in area 2019/2004 | Change in emissions 2019/2004 |
|------------------|-------------------------|---------------------------------------|-------------------------|---------------------------------------|-----------------------------|----------------------------------|
| | Deforestation area (ha) | Gross emission (tCO ₂ /ha) | Deforestation area (ha) | Gross emission (tCO ₂ /ha) | | |
| 2016-2017 | 35,425.69 | 3,709,137.07 | 35,948.28 | 3,629,784.82 | 1.48% | -2.14% |

Source: own estimates

The Pantanal boundaries were slightly reduced from IBGE (2004) (15,130,300 ha) to IBGE (2019) (15,098,800 ha) but the changes in emissions was second to the Caatinga biome. The change in emissions ranged from –9.04% to 19.92% during the reference period.

Is important to note that none of the observed changes imply under or over estimations of the FREL, since there is no overlap between the geographical areas of the biomes or gaps in Brazil's geographical coverage, and all emissions are estimated. It just a matter of allocation within the biomes. Nevertheless, the change in the boundaries of the biomes resulted in the selection of different EF per phytophysiognomies and consequently in different impacts on the emissions. For example, in the Pantanal biome in 2020-2021 area deforested have increased by 1%; but emissions have decreased by 2%.

5.4.1.2. Implications of the use of the MMU of 1 ha in the estimation of the area deforested in the Amazon biome

The most significant difference between the estimates of gross deforestation in this national FREL submission and those in the 4th National GHG Inventory refers to the use of a MMU of 1 ha for the Amazon biome, instead of the MMU of 6.25 ha used in the 4th National GHG Inventory. The PRODES program conducted by INPE and that provides the official annual estimates of gross deforestation for the Legal Amazonia area uses MMU of 6.25 ha to ensure consistency in the timeseries since 1988. At that time, the estimates were obtained from the analysis of the deforestation polygons copied from the satellite image to transparent overlays, and 6.25 ha MMU corresponded to 1 mm² in paper. To ensure consistency throughout the entire annual time series since 1988, INPE continues to use the MMU of 6.25 ha.

The use of a MMU of 1 hectare responds to the one of the areas for future improvements identified during previous technical analysis²⁸. The impact of including deforested areas between 1 ha and 6.25 ha is an average increase of 11.3 % in total deforested area and an average increase in CO₂e emissions of 11.2 % in the period from 2016/2017 to 2020/2021 (Figures below).

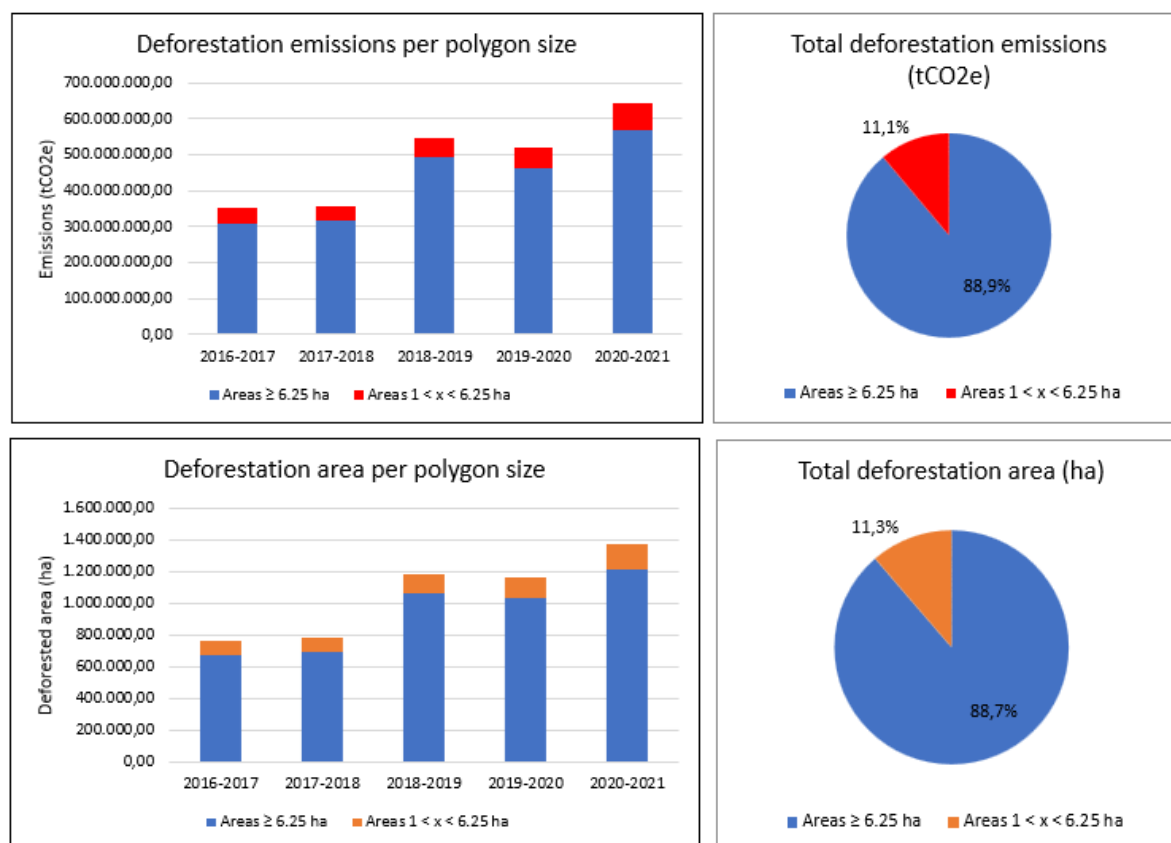

Figure 29 – Impact of including deforested areas between 1 ha and 6.25 ha in deforested areas and GHG emission estimates

Source: own calculations

5.4.2. Consistency with other forest information reported internationally by Brazil

Although there is no requirement under the UNFCCC REDD+ that Brazil ensures consistency with forest information reported to other international bodies, Brazil plans to ensure this consistency in future submissions, in particular, between the national inventory report of anthropogenic emissions by sources and removals by sinks of GHG to the Paris Agreement, future REDD+ submissions, and information reported to the Global Forest Resources Assessments (FRA - refer to **Box 9**).

²⁸ Paragraph 20 of Report of the technical assessment of the proposed forest reference emission level of Brazil submitted in 2018 (FCCC/TAR/2018/BRA). Available at: https://unfccc.int/sites/default/files/resource/tar2018_BRA.pdf

Brazil plans to evaluate the use, across all submissions, of biomass and carbon stocks derived from the **National Forest Inventory (NFI)**²⁹. Nowadays, the NFI has been developed at the sub-national level. The following States have completed and validated the results:

- Ceará
- Federal District
- Espírito Santo
- Paraíba
- Paraná
- Rio de Janeiro
- Rio Grande do Norte
- Rondônia
- Rio Grande do Sul
- Santa Catarina
- Sergipe

Results are updated regularly at NFI website³⁰ and the Global Forest Resources Assessments (FRA) platform³¹.

Box 9 – Brazil's participation in the Global Forest Resources Assessments (FRA)

Forest Resources Assessments (FRA) are produced by countries reports based on data analysis done approximately every two years in advance of a reference year. Countries must carry out projections for the reference year based on the data available up to the date of preparation of the report.

In 2018, the Brazilian National Forest Inventory (NFI) had collected data approximately in 53% of the national territory. Data were collected in all biomes with the exception of the Pantanal biome.

Although the first NFI collection cycle was not completed, Brazil opted to use the NFI data for the FRA 2020 communication. The data used for biomass and carbon stocks estimation were obtained from Brazil NFI, collected until and available by December 2018. This was the first time that the FRA carbon stocks were calculated with data from the NFI.

In the NFI, information on carbon stocks is presented by forest typology according to IBGE Brazilian vegetation map and considering the boundaries of the 6 Brazilian biomes (Amazonia, Cerrado, Atlantic Forest, Caatinga, Pampa and Pantanal). For forest extension, data from IBGE Brazilian vegetation map was also used, which gives the information about

²⁹ More information about the NFI (in Portuguese) is available at: <https://www.gov.br/agricultura/pt-br/assuntos/servico-florestal-brasileiro/ifn-inventario-florestal-nacional>

³⁰ Latest NFI information is available at: <https://snif.florestal.gov.br/pt-br/inventario-florestal-nacional-ifn/ifn-dados-abertos>

³¹ Information presented by Brazil to the FRA is available at: <https://fra-data.fao.org/BRA/fra2020/home/>

the original vegetation cover all over the country according to the national vegetation classification categories.

The NFI is based on a systematic sampling design, with clusters of four sub units of 20m x 50m each, distributed in a national grid of 20 km x 20 km. Data of living trees over 10 cm DBH were processed for calculating average carbon stocks (ton/ha) for each biome and for each forest type within each biome, using available and published allometric equation fitted for forest types. For the vegetation types with low number of clusters in the biome, total samples for all biomes of that specific forest type were used. Carbon stock was estimated using the default IPCC factor of 0.49 applied to the biomass values. To retrieve field data for forest type, NFI used the same vegetation map used to estimate forest extension; and for estimating the total biomass carbon stock each forest type, values were multiplied by its correspondent area given by the map. Although the NFI has information collected on soil and litter pools, such data were not used because it was not proper analyzed up to December 2018.

Only for the Pantanal biome, where there was no NFI data collected, the data used was the same used for the 2015 FRA submission (i.e., data based on bibliography references).

There is methodological consistency between the national GHG inventory and the Brazil's FRA. The vegetation map used is the same, as well as the definition of forest; both coincide with those used by the Brazilian Forestry Service. Nevertheless, There is a time difference in the preparation and reference dates of these reports, which causes some delay in the alignment of these activities. Usually, the FRA are made on advance and the national GHG inventory are made after the reference year.

It should be noted that the NFI is still under development; and its preliminary results for carbon stocks need to be further assessed, in order to better understand the differences with the current values used in the national GHG inventory.

The use of data (biomass and carbon stocks) derived from the National Forest Inventory could potentially result in more accurate GHG emissions estimates, but it is expected to result in differences compared to the current estimates. To illustrate the impact of using biomass and carbon stocks values derived from the NFI, a preliminary analysis was made using current available NFI values for selected phytophysiognomies in Pampa and Atlantic Forest biomes. The results are presented in the following tables.

Table 26 – Gross emissions from deforestation estimated in this national FREL and using data from the NFI to estimate total carbon stocks and related CO₂ emissions in Decidual Seasonal Forest in the Pampa biome, and the percent differences

| Period | Gross emissions due to deforestation (t CO ₂) | | Difference |

6. Results

Brazil's national FREL is the sum of the estimated GHG emissions for each of the six Brazilian biomes. The following sections presents the results of GHG emissions for each of the Brazilian biomes, estimated according to the methodology and information previously described.

6.1. Amazon biome

The following tables and figure present the area deforested in each annual period of the reference period and corresponding net GHG emissions associated with deforestation and forest degradation in the Amazon biome.

Table 30 – CO₂ removals and GHG emissions associated with gross deforestation and degradation in the Amazon Biome

| Period | Removals by secondary vegetation (tonnes CO ₂ yr ⁻¹) | Deforestation emissions (tonnes CO ₂ eq yr ⁻¹) | Degradation emissions due to fire in managed land (tonnes CO ₂ eq yr ⁻¹) | Degradation emissions due to disordered logging (tonnes CO ₂ yr ⁻¹) |
|------------------|---|---|---|--|
| 2016-2017 | -167,812,819 | 351,860,631 | 42,107,135 | 7,160,053 |
| 2017-2018 | -167,812,819 | 358,656,510 | 12,392,623 | 4,991,741 |
| 2018-2019 | -167,812,819 | 546,672,701 | 16,644,544 | 17,376,069 |
| 2019-2020 | -167,812,819 | 521,509,008 | 45,788,437 | 20,682,306 |
| 2020-2021 | -167,812,819 | 645,550,074 | 9,144,334 | 29,253,071 |

OBS: the differences with results presented in previous REDD+ technical annex is due to changes made in this submission (listed in section 3.5.1), including response to recommendations from past technical analysis (presented and explained in section 8.9). In particular, due to the use of updated values of emission factors from EBA, changes in the biome boundaries and the inclusion of deforestation areas smaller than 6.25 ha.

6.7. Brazil's National FREL

Brazil's national FREL is estimated as the sum of the gross average GHG emissions from Atlantic Forest, Caatinga and Pantanal biomes and the net GHG emissions (in tonnes CO₂e-q) from Amazon and Cerrado biomes - **Table 37** and **Figure 42**.

Table 37 – Brazil's national FREL for 2016-2017 / 2020-2021 period

| Biome | Average emissions (tCO ₂ eq) | Type |
|-------------------|---|-----------------|
| Amazônia | 358,036,814 | Net emissions |
| Cerrado | 32,001,633 | |
| Atlantic forest | 34,660,570 | Gross emissions |
| Caatinga | 26,242,349 | |
| Pampa | 4,062,706 | |
| Pantanal | 6,036,837 | |
| FREL (sum) | 461,040,910 | |

1902

1903

Based on this FREL, Brazil intends to seek for results-based payments resulting from the implementation of its policies and plans for REDD+.

1904

1905

Box 10- Relevant policies and plans for REDD+

Brazil’s sovereign commitment to the protection of native vegetation and the integrity of the climate system for the well-being of present and future generations was reiterated by [Law No. 12.651/2012](#) (Forest Code). Also, a series of policies, laws, regulations, actions and initiatives from various stakeholders contribute to REDD+ implementation, both at the national and biome/regional level. The National Strategy for REDD+ (ENREDD+) was set out in 2015 with the objective to contribute to scale up the implementation of policies to reduce deforestation and forest degradation from the Amazon and Cerrado biomes to the national level.

The action plans to prevent and control deforestation in the Amazon and in the Cerrado were the main mediators instruments of public policies in the territory. Since 2004 (in the case of the Amazon) and since 2010 (in the case of the Cerrado), the efforts made have shown meaningful results in terms of reducing deforestation rates. Nevertheless, there has been an upward trend in deforestation in the Amazon, which reflects a certain exhaustion of previous plans, with the need to develop more effective solutions to prevent and counter illegal deforestation. In this context, considering the search for new solutions in addition to those that had been performing well, in 2019 there was a transition to the new Plan for the

Control of Illegal Deforestation and Recovery of Native Vegetation, which encompasses the entire territory, approved by the Commission for the Control of Illegal Deforestation and Recovery of Native Vegetation – CONAVEG (Decree No. 10.142/2019). The purpose of the new plan is to reduce illegal deforestation and degradation of native vegetation through positive measures that impact on new dynamics and encourage sustainable production models as an alternative to the suppression of native vegetation.

The National Plan for the Control of Illegal Deforestation and Recovery of Native Vegetation provides guidelines for combating deforestation based on three cross-cutting themes: business environment, innovation and technological solutions, and financing for sustainable practices. In order to support coordination and integration of these themes, the Plan was structured in 05 major axes: (i) zero tolerance to deforestation and firefighting, (ii) land tenure regularization, (iii) territorial management, (iv) bio-economy, (v) payment for environmental services.

It is also worth to mention the approval of the National Policy for Payments for Environmental Services ([Law 14.119/2021](#)) which has been under discussion within the Technical Committee for its regulatory procedures.

Specifically about results-based payments, the National REDD+ Committee (Decree No. 10.144/2019) took important steps in the implementation of REDD+ beyond the Amazon, with the approval, in 2022, of the fundraising limits and eligibility criteria for the entities of the Cerrado biome, based on the results for reducing deforestation in this biome verified by the UNFCCC.

6.8. Uncertainties

The following tables presents the uncertainty estimates for gross GHG emissions associated with deforestation, degradation, and removals from secondary vegetation. Values presented in percent uncertainties around the estimated value, representing a 95% confidence interval.

Table 38 – Uncertainty of gross CO₂ emissions from deforestation

| Year | Amazon | Cerrado | Caatinga | Atlantic Forest | Pampa | Pantanal |
|---------|--------|---------|----------|-----------------|-------|----------|
| 2017 | 8.3 | 13 | 18 | 18 | 18 | 24 |
| 2018 | 8.0 | 12 | 19 | 15 | 18 | 25 |
| 2019 | 8.3 | 13 | 17 | 17 | 17 | 23 |

Source: own calculations

As mentioned in the 2019 Refinement to the 2006 IPCC Guidelines (footnote in 3.20 of Vol. 1) the option for expressing uncertainties in percent terms allows the results to be presented in a user-friendly way. However, caution should be exercised in the interpretation of the results in cases where the point estimate is very small when compared with the size of the confidence interval (e.g., a sector or inventory where removals and emissions are of similar sizes).

That is exactly the case for the net emissions in the Cerrado biome where gross emissions and removals from regeneration have the same order of magnitude. For more clear understanding we also include the uncertainty of the net emissions expressed as the 95% confidence interval.

Table 43 – Uncertainty of net emissions expressed as 95% interval around the mean

| Year | Confidence Interval | | Confidence Interval | |
|-----------|-----------------------------|-------------|---------------------|------------|
| | Amazon | | Cerrado | |
| | (tonnes CO ₂ eq) | | | |
| 2016-2017 | 128.841.401 | 333.042.673 | -8.160.194 | 71.656.486 |

8. Annex: Additional Information

8.1. Additional information related to deforestation activity data

The mapping of the areas deforested in each biome followed the methodology developed and used in **PRODES-Amazônia** (Almeida, et al., 2020) and **PRODES-Cerrado** (INPE, 2018), in order to ensure that the identification of deforestation polygons is consistent throughout all Brazilian territory. In general, the methodology involves visual analysis followed by manual vectorization of deforestation using medium-resolution satellite images (Landsat type) - **Figure 43**.

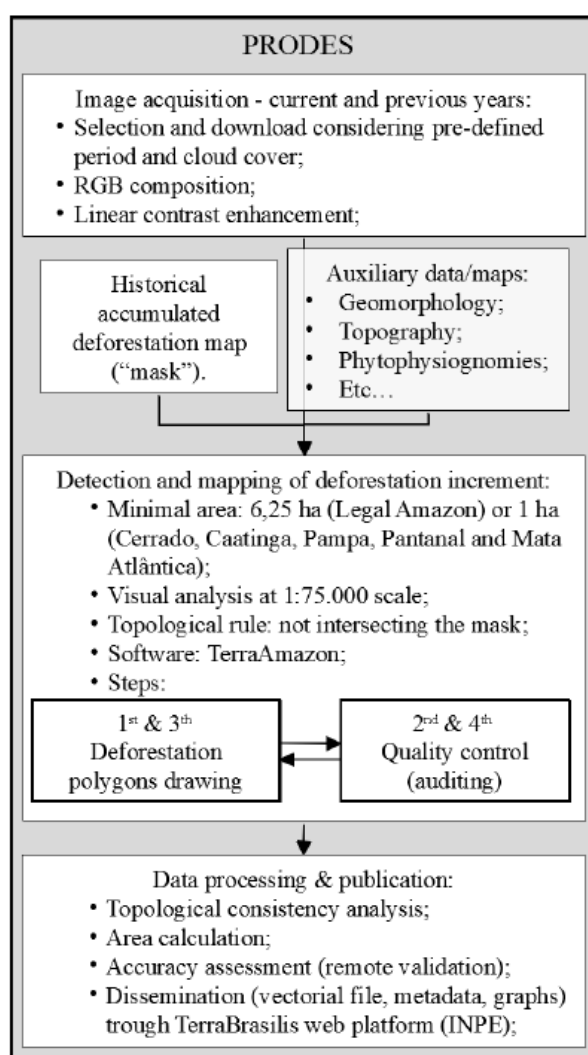

Figure 43 – General description of PRODES methodology

Source: Adapted from Almeida, et al., 2020

The images used to identify the deforested polygons were selected following a priority period in order to have regular annual intervals. The defined periods include a priority quarter associated with an extended period - which adds one or two months beyond the priority quarter.

Table 44 – Satellite images selection period

| Biome | Priority period | Extended period |
|------------------------------|----------------------------------|---|
| Amazon | July-August-September | July-August-September-October-November |
| Cerrado | July-August-September | June-July-August-September |
| Caatinga | August-September-October (ASO) | July-August-September-October-November-December |
| Pampa | September-October-November (SON) | August-September-October-November-December |
| Pantanal | July- August-September (JAS) | July-August-September-October |
| Atlantic Forest - north | October-November -December (OND) | September-October-November-December |
| Atlantic Forest south-center | June-July-August (JJA) | June-July-August-September |

Source: INPE/FUNCATE

Table 45 – Average interval of days considered in the selection of images, for each biome, and period of analysis period

| Period | Average interval of days | | | | | |
|-----------|--------------------------|---------|-----------------|----------|-------|----------|
| | Amazon | Cerrado | Atlantic Forest | Caatinga | Pampa | Pantanal |
| 2016-2017 | 361 | 370 | 377 | 408 | 360 | 364 |
| 2017-2018 | 364 | 352 | 374 | 358 | 369 | 368 |
| 2018-2019 | 389 | 378 | 356 | 388 | 381 | 363 |
| 2019-2020 | 362 | 369 | 343 | 356 | 323 | 367 |
| 2020-2021 | 367 | 365 | 360 | 330 | 392 | 369 |

Source: FUNCATE

For each of the biomes, there was a team of qualified interpreters that generated deforestation data for each of the periods, thus reducing potential inconsistencies in the identification of deforestation patterns in each of the maps produced.

A reference map was generated from satellite imagery for the reference period and each biome, indicating the accumulated areas of deforestation and non-deforestation (considered natural areas). From this reference map, according to the methodology presented in **Figure 43**, areas were identified and mapped at the scale of 1:100,000. **Table 46** shows the number of scenes for each biome for each year analyzed. The sum of the areas of the deforestation polygons identified within a given geographical extent (e.g., biome) is referred to as increment of deforestation.

Deforestation increments in forest areas in the period 2016 to 2021 constitute the activity data to estimate CO₂ emissions from deforestation. Brazil's National FREL considers the increments of deforestation (ha/yr) for each of the following periods: 2016-2017, 2017-2018, 2018-2019, 2019-2020, 2020-2021.

Table 46 – Number of scenes analyzed in each annual period of the historical series, for each biome

| Biome | Number of Landsat scenes used to cover the biome |
|-----------------|--|
| Amazon | 203 |
| Cerrado | 126 |
| Atlantic Forest | 89 |
| Caatinga | 52 |
| Pampa | 17 |
| Pantanal | 16 |

8.2. Additional information related to forest degradation activity data

Spatial data on forest degradation are available through INPE's DETER System, whose methodology is described in Almeida et al. (2022). In summary, DETER's methodology is based on the visual analysis of CBERS WFI satellite images in color composites of bands 5 (R), 4 (G) and 3 (B) and shadow fraction and vegetation images acquired through linear model analysis of spectral mixture, in addition to multi-time series of Landsat and CBERS images (Almeida, et al., 2022).

Degradation polygons in the DETER system are associated with logging (orderly/geometric and irregular/disordered) and "fire scars". The area of the polygons identified as degradation in each annual period may continue to be exploited or burned in subsequent years and may eventually be deforested, either partially or totally. Therefore, a given polygon classified as degraded may be reclassified as deforested in subsequent years.

Areas of selective logging and "fire scars" in Amazon biome are available for all years of the reference period.

8.2.1. Orderly and disordered logging

Mapping classes for logging follow distinct patterns that result from the very the way the wood exploration is carried out. DETER classified the logging activities into two categories: irregular/disordered logging and regular/orderly (Almeida, et al., 2022).

1. **Irregular/disordered logging**: it is considered a common type of wood extraction, where trees of commercial interest are removed without prior planning, identified unorderly shape of roads and extensions inside the forest and with the presence of storage patios with disordered dimensions and arranged randomly arranged.
2. **Regular/orderly logging**: it is considered to be related to an exploration based on some type of management plan (legal or not), in which one perceives the spatial organization of elements such as roads and storage patios inside the forest.

Only logging with disordered geometric patterns available in the DETER System was considered in this FREL submission as part of forest degradation. Once the SINAFLOR data are available (see **Box 7**), it will be possible to verify if the non-regular logging is indeed associated with forest degradation and not to management plans. The data will be instrumental to further discriminate forest degradation activities from those associated with approved management plans.

It is noteworthy that the definition of the logging classes is based only on the interpretation of the image based on the observed patterns of logging, and there is a limited capacity to identify the number of trees felled per hectare, volume extracted and secondary impact inside the forest or the legality of the intervention. **Figure 44** presents examples of alerts related to logging activities following DETER methodology (Almeida et al., 2022).

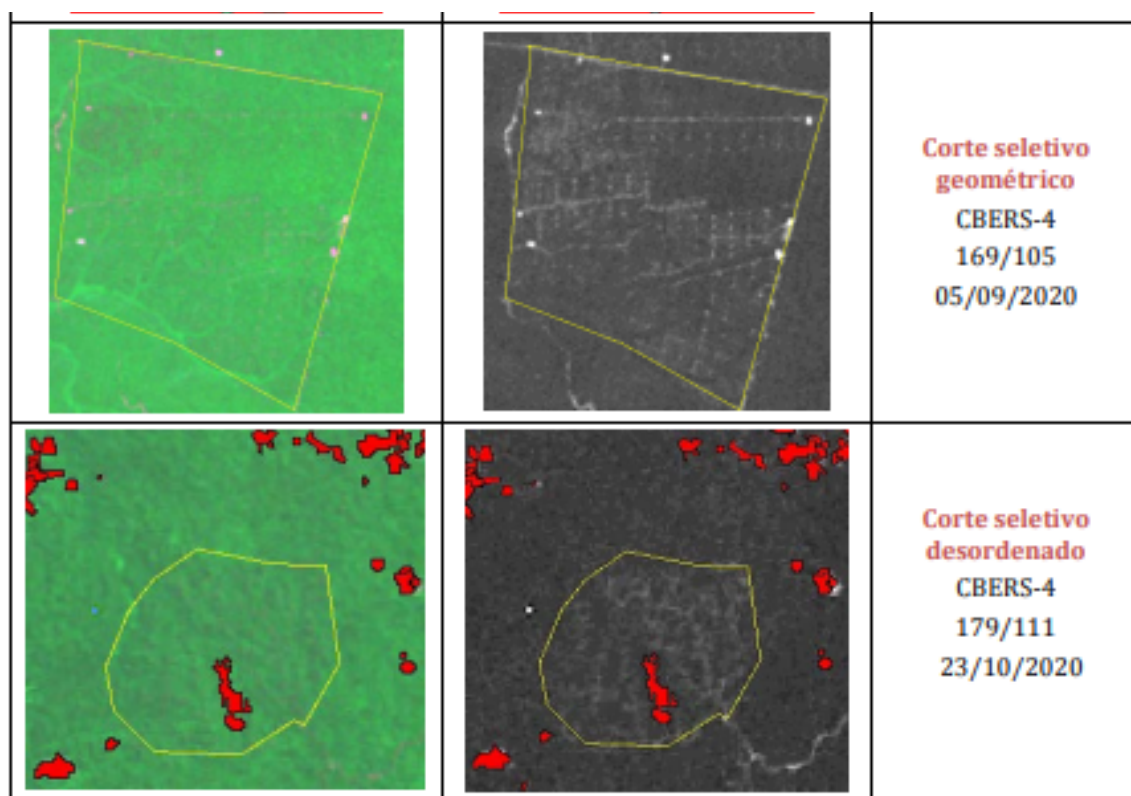

Figure 44 – Example of orderly (up) and disordered (bottom) logging from DETER system

Source: DETER

8.2.2. Fire scar

According to Valeriano et al. (2016) a “**fire scar**” an area that presents spectral characteristics associated with a fire occurrence. **Figure 45** presents an example of an area affected by fire that was mapped under as a DETER “fire scar”.

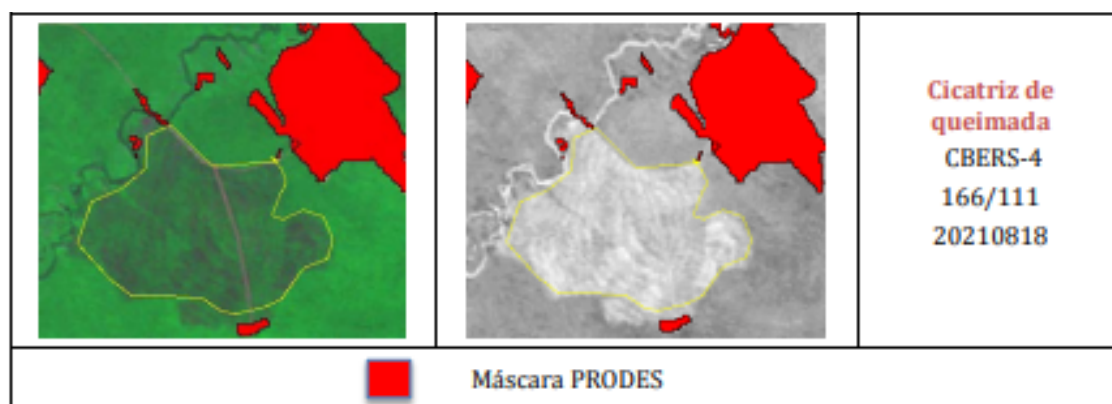

Figure 45 – Example of a “fire scar” in the DETER system

Source: DETER

2213

2214 8.3. Additional information related to the areas of natural 2215 forest regeneration (secondary vegetation) 2216

2217 8.3.1. Secondary vegetation – Amazon 2218

2219 To estimate net emissions in the Amazon biome, the areas of natural forest regeneration in
2220 areas previously deforested in the Amazon biome were first obtained from the **TerraClass**
2221 **Project**, were assessed. Unlike PRODES and DETER, such mapping is not produced with the
2222 same frequency as PRODES and DETER data, and information is only available for years 2014
2223 and 2020.
2224

2225 According to Almeida, et al. (2016), areas of secondary vegetation consist of those forest
2226 areas that have been deforested and later abandoned for natural regeneration. Areas
2227 mapped as secondary vegetation may be in different stages of regeneration: initial, when the
2228 canopy is homogeneous and few species are found; or advanced, when the heterogeneity of
2229 the canopy and the diversity of species is similar to the original forest (Vieira, et al., 2003).
2230

2231 For 2014, the methodology used to map areas of secondary vegetation was based on the use
2232 of fraction images and color composites of Landsat-5/TM 3, 4 and 5 bands. Using the images
2233 and a linear mixing model, it was possible to identify a threshold above which the soil cover
2234 is dominated by secondary vegetation. These values varied for each image and once the
2235 spectral pattern was identified, image slicing technique was applied to create a thematic
2236 image (Almeida C. A., Valeriano, Escada, & Rennó, 2010).
2237

2238 For 2020 the methodology was based on a random stratified sampling in two stages. Initially,
2239 the Amazon biome was stratified by state and, later, by percentage of deforested area. To
2240 obtain the strata, the percent data of secondary vegetation mapped by TerraClass in the years
2241 2014, 2012 and 2010 were used. After the stratification, parcels with 20 km by 20 km were
2242 randomly selected and training samples collected and subject to automatic classification,
2243 performed by a machine learning algorithm on cloud-based geospatial analysis platform
2244 Google Earth Engine (GEE). The classification used all available images for the period between
2245 June 2020 and October 2020, obtained by Sentinel-2/MSI satellite. Based on the area mapped
2246 in each of the parcels, the areas of secondary vegetation for the nine Amazon States and,
2247 later, for the Legal Amazon were estimated by direct expansion. Next, a subset of parcel
2248 training samples was used to map the secondary vegetation area to the State, providing
2249 spatially explicit areas.
2250

2251 8.3.2. Secondary vegetation – Cerrado 2252

2253 Secondary vegetation defined by TerraClass Cerrado is related to a natural vegetation
2254 formation, with predominance of savanna forest (*“cerradão”*) with trees with height between
2255 15 and 18 meters and characterized by trees and shrubs with tortuous trunks that had been

previously deforested. In the Cerrado biome, secondary vegetation data are available only for the years 2018 and 2020.

8.4. Detail description for estimating GHG emissions/removals in the Amazon biome

The operational procedures, based on the methodological approach described in page 56, used to estimate GHG emissions due to deforestation, forest degradation and removals from secondary vegetation growth in the Amazon biome are detailed below. Overview of phase 1 is presented in **Figure 46**, where spatial data is assembled and spreadsheets are acquired to next calculation steps.

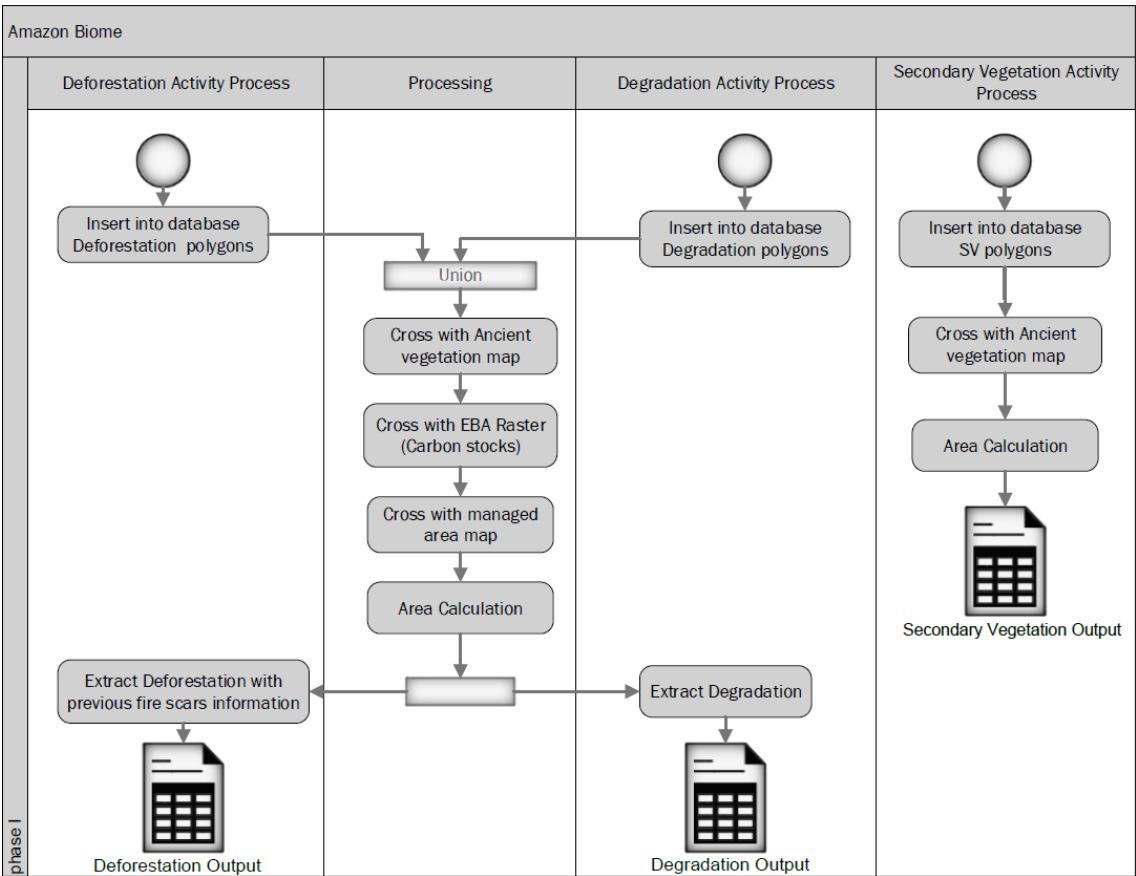

Figure 46 – Phase 1 workflow in GIS to deliver deforestation, degradation and secondary vegetation outputs to further phases

Source: own elaboration

8.4.1. Deforestation output – Amazon biome

• PHASE 1 – GIS operations

The 1st phase involves several spatial operations in a GIS environment (especially TerraAmazon software), with the aim to consolidate and merge maps presenting deforestation areas and other important information. The following steps (**Erro! Fonte de referência não encontrada.**) summarize these operations:

- **Step 1: Vectorial data gathering and verification (database creation), considering:**
 - a. PRODES maps presenting polygons of native vegetation conversion increments for the periods 2016-2017, 2017-2018, 2018-2019, 2019-2020 and 2020-2021
 - b. DETER degradation maps presenting fire scars and selective logging areas
 - c. Biomes boundaries (**Figure 1**)
 - d. Ancient native vegetation map (**Figure 9**)
 - e. Managed areas map

Verifications consists in a routine of procedures to identify topology errors (such as overlaps and gaps) and lack of information.
- **Step 2:** Spatial operations execution to join step 1 data and then to filter only deforestation polygons (i.e., native vegetation clearing occurring in forest phytophysionomies according to the ancient native vegetation map).
- **Step 3:** Association of the emission factors (i.e., carbon stocks per unit area) to each deforestation polygon through the extraction of the spatial average value from the EBA raster map (4th National GHG Inventory maps presenting each carbon pool).
- **Step 4:** Exportation of an electronic spreadsheet containing, for each annual period of the reference period, the deforestation polygons and their corresponding phytophysionomies and associated carbon stocks for above-ground biomass, below-ground biomass, dead wood and litter - **Table 47**.

Table 47 – Outcome of phase 1 “GIS operations” for the Amazon deforestation component, which is the input for next phases.

Figure 47 – Illustrative representation of the electronic spreadsheet output from Phase 1

Source: own elaboration

Each line of the spreadsheet represents a group of polygons with the same characteristics, except for their individual area. The "area_ha" attribute represents the sum of the individual deforested polygons areas. Such aggregation was necessary due to the large amount of data generated for the Amazon biome, which are not supported by Excel.

- PHASE 2 – Emissions calculations**

Emissions calculations were performed in chronological order, according to the occurrence of degradation and/or deforestation activities, always applying the degradation losses before losses due to deforestation within the same year. The following steps were followed³²:

- **Step 1:** Calculation of carbon stocks available in $t0$ (in tonnes of C, i.e., tC/ha stock values already multiplied by areas in ha) by total and carbon pools:
 - Column U: total C stock $t0$ $[=S3*T3]$
 - Column V: aerial C stock $t0$ $[=(O3+Q3+R3)*T3]$
 - Column W: above ground C stock $t0$ $[=O3*T3]$
- **Step 2:** Calculation of C, CH₄ and N₂O emissions and other losses due to degradation in 2017:
 - Column X: C emissions due to fire in managed lands
 - Column Y: CH₄ emissions due to fire in managed lands
 - Column Z: N₂O emissions due to fire in managed lands
 - Column AA: C emissions due to disordered logging (CS)
 - Column AB: C loss due to fire in unmanaged lands
 - Column AC: C loss due to orderly logging (CSR)
- **Step 3:** Calculation of remaining carbon stocks after degradation in 2017, representing carbon stocks available for deforestation in 2017:
 - Column AD: total C stock $t1$
 - Column AE: aerial C stock $t1$
 - Column AF: above ground C stock $t1$
- **Step 4:** Calculation of C, CH₄ and N₂O emissions due to deforestation in 2017:
 - Column AG: C emissions due to deforestation
 - Column AH: CH₄ emissions due to deforestation (resulting from slash and burn)
 - Column AI: N₂O emissions due to deforestation (resulting from slash and burn)
- **Step 5:** Calculation of carbon stocks available after 2017, representing carbon stocks available for degradation in 2018:
 - Column AJ: aerial C stock $t2$
 - Column AK: above ground C stock $t2$
- **Step 6:** Calculation of C, CH₄ and N₂O emissions and other losses due to degradation in 2018:
 - Column AL: C emissions due to fire in managed lands
 - Column AM: CH₄ emissions due to fire in managed lands
 - Column AN: N₂O emissions due to fire in managed lands
 - Column AO: C emissions due to disordered logging (CS)
 - Column AP: C carbon loss due to fire in unmanaged lands
 - Column AQ: C carbon loss due to orderly logging (CSR)

³² Refer to file: "P3h_FREL_AMAZONIA_EMITSOES_DESMATAMENTO_1ha-6ha_Cenario3_v20201030.xlsx"

- 2367 ○ **Step 7:** Calculation of carbon stocks available after 2018 degradation, representing
2368 carbon stocks available for deforestation in 2018:
2369 Column AR: total C stock t_3
2370 Column AS: aerial C stock t_3
2371 Column AT: above ground C stock t_3
2372
- 2373 ○ **Step 8:** Calculation of C, CH₄ and N₂O emissions due to deforestation in 2018:
2374 Column AU: C emissions due to deforestation
2375 Column AV: CH₄ emissions due to deforestation (resulting from slash and burn)
2376 Column AW: N₂O emissions due to deforestation (resulting from slash and burn)
2377
- 2378 ○ **Step 9:** Calculation of carbon stocks available after 2018, representing carbon stocks
2379 available for degradation in 2019:
2380 Column AX: aerial C stock t_4
2381 Column AY: above ground C stock t_4
2382
- 2383 ○ **Step 10:** Calculation of C, CH₄ and N₂O emissions due to degradation in 2019:
2384 Column AZ: C emissions due to fire
2385 Column BA: CH₄ emissions due to fire
2386 Column BB: N₂O emissions due to fire
2387 Column BC: C emissions due to disordered logging (CS)
2388 Column BD: C carbon loss due to fire in unmanaged lands
2389 Column BE: C carbon loss due to orderly logging (CSR)
2390
- 2391 ○ **Step 11:** Calculation of carbon stocks available after 2019 degradation, representing
2392 the carbon stocks available for deforestation in 2019:
2393 Column BF: total C stock t_5
2394 Column BG: aerial C stock t_5
2395 Column BH: above ground C stock t_5
2396
- 2397 ○ **Step 12:** Calculation of C, CH₄ and N₂O emissions due to deforestation in 2019:
2398 Column BI: C emissions due to deforestation
2399 Column BJ: CH₄ emissions due to deforestation (resulting from slash and burn)
2400 Column BK: N₂O emissions due to deforestation (resulting from slash and burn)
2401
- 2402 ○ **Step 13:** Calculation of carbon stocks available after 2019, representing carbon stocks
2403 available for degradation in 2020:
2404 Column BL: aerial C stock t_6
2405 Column BM: above ground C stock t_6
2406
- 2407 ○ **Step 14:** Calculation of C, CH₄ and N₂O emissions due to degradation in 2020:
2408 Column BN: C emissions due to fire
2409 Column BO: CH₄ emissions due to fire
2410 Column BP: N₂O emissions due to fire
2411 Column BQ: C emissions due to disordered logging (CS)
2412 Column BR: C loss due to fire in unmanaged lands
2413 Column BS: C loss due to orderly logging (CSR)

- **Step 15:** Calculation of carbon stocks available after 2020 degradation, representing the carbon stocks available for deforestation in 2020:
 - Column BT: aerial C stock t_7
 - Column BU: above ground C stock t_7
 - Column BV: above ground C stock t_7
- **Step 16:** Calculation of C, CH₄ and N₂O emissions due to deforestation in 2020:
 - Column BW: C emissions due to deforestation
 - Column BX: CH₄ emissions due to deforestation (resulting from slash and burn)
 - Column BY: N₂O emissions due to deforestation (resulting from slash and burn)
- **Step 17:** Calculation of carbon stocks available after 2020, representing carbon stocks available for degradation in 2021:
 - Column BZ: aerial C stock t_8
 - Column CA: above ground C stock t_8
- **Step 18:** Calculation of C, CH₄ and N₂O emissions due to fire degradation in 2021:
 - Column CB: C emissions due to fire
 - Column CC: CH₄ emissions due to fire
 - Column CD: N₂O emissions due to fire
 - Column CE: C emissions due to disordered logging (CS)
 - Column CF: C loss due to fire in unmanaged lands
 - Column CG: C loss due to orderly logging (CSR)
- **Step 19:** Calculation of carbon stocks available after 2021 degradation, representing the stocks available for deforestation in 2021:
 - Column CH: Total C stock t_9
 - Column CI: above ground C stock t_9
 - Column CJ: above ground C stock t_9
- **Step 20:** Calculation of C, CH₄ and N₂O emissions due to deforestation in 2021:
 - Column CK: C emissions due to deforestation
 - Column CL: CH₄ emissions due to deforestation (resulting from slash and burn)
 - Column CM: N₂O emissions due to deforestation (resulting from slash and burn)

The following table presents a numerical example of the calculations that have been carried out. Is important to note the evolution of total carbon stocks. In green: initial total carbon stocks; in blue: total carbon stocks after degradation events or not; in yellow: emissions due to deforestation whose values are associated with the reduced carbon stocks after previous degradation.

2457 **Table 48 – Example of GHG emissions for an area presenting a trajectory that passes**
2458 **through degradation by fire to deforestation³³**

8.4.2. Degradation output – Amazon biome

• PHASE 1 – GIS operations

The 1st phase involves several “georeferenced operations” using SIG tools, with the aim to consolidate all different degradation activity data. As result, a spreadsheet was obtained, containing the information presented in **Table 49**. Each line of the spreadsheet represents a group of polygons with the same characteristics, with the exception of the area (hectares). The area represents the sum of the individual polygons. Such aggregation was necessary due to the large amount of data.

Table 49 – Amazon degradation output main parameters

| Variable name | Description | Unit | Spreadsheet column | Source |
|------------------------|---|-------|--------------------|--|
| Biome | Biome classification: Amazon | n/a | A | IBGE, 2019 |
| Main_class | REDD+ activity classification: “DEGRAD” meaning “degradation” | n/a | B | DETER |
| deter2017 | Degradation classification in corresponding year: - Fire (“burn scar”) - Disordered logging (“CS”) - orderly logging (“CSR”) | n/a | C | |
| deter2018 | | n/a | D | |
| deter2019 | | n/a | E | |
| deter2020 | | n/a | F | |
| deter2021 | | n/a | G | |
| status | | | H | |
| source_inv | Corresponding biome classification in the 4 th GHG National Inventory | n/a | I | 4 th GHG National Inventory |
| Phytophysiology | Ancient vegetation phytophysiology | n/a | J | |
| category | Vegetation category: Forest (F) | n/a | K | |
| Managed_land | indicates whether the polygon is situated in a managed area (“t” = true) or not (“f” = false) | | L | |
| EBA_cagb | Carbon content – above ground biomass carbon pool | tC/ha | M | EBA |
| EBA_cbgb | Carbon content – below ground biomass carbon pool | tC/ha | N | |
| EBA_cdw | Carbon content – dead wood carbon pool | tC/ha | O | |

| Variable name | Description | Unit | Spreadsheet column | Source |
|---------------|--------------|-------|--------------------|---------------|
| EBA_ctotal | Total carbon | tC/ha | Q | |
| area_ha | Polygon area | ha | R | Own estimates |

Source: Electronic spreadsheet "1c_Amazon_Emissions_Output_Degradation.xls"

• PHASE 2 – Emissions calculations

Emissions calculations were performed in chronological order, according to the occurrence of degradation processes (fire and/or disordered logging). The following steps have been followed³⁴:

- **Step 1:** Calculation of carbon stocks available in *t0* (tons of C, i.e., tC/ha stock values already multiplied by areas (in ha)) by total and carbon pools:
 - Column S: total C stock *t0*
 - Column T: aerial C stock *t0*
 - Column U: above ground C stock *t0*
- **Step 2:** Calculation of C, CH₄ and N₂O emissions from degradation due to fire in managed forest areas or disordered logging (CS) in 2017:
 - Column V: C emissions due to fire in managed lands
 - Column W: CH₄ emissions due to fire in managed lands
 - Column X: N₂O emissions due to fire in managed lands
 - Column Y: C emissions due to disordered logging (CS)
 - Column Z: C loss due to fire in unmanaged lands
 - Column AA: C loss due to orderly logging (CSR)
- **Step 3:** Calculation of remaining carbon stocks after degradation processes in 2017, defining the carbon stocks available for potential degradation in 2018:
 - Column AB: aerial C stock *t1*
 - Column AC: above ground C stock *t1*
- **Step 4:** Calculation of C, CH₄ and N₂O emissions from degradation due to fire in managed forest areas or disordered logging (CS) in 2018:
 - Column AD: C emissions due to fire
 - Column AE: CH₄ emissions due to fire
 - Column AF: N₂O emissions due to fire
 - Column AG: C emissions due to disordered logging (CS)
 - Column AH: C loss due to fire in unmanaged lands
 - Column AI: C loss due to orderly logging (CSR)

³⁴ Refer to file: "1c_Amazon_Emissions_Output_Degradation.xls "

- 2528 ○ **Step 5:** Calculation of carbon stocks available after degradation processes in 2018,
 2529 defining the carbon stocks available for potential degradation in 2019:
 2530 Column AJ: aerial C stock t_2
 2531 Column AK: above ground C stock t_2
 2532
- 2533 ○ **Step 6:** Calculation of C, CH₄ and N₂O emissions due to degradation by fire in managed
 2534 forest areas or disordered logging (CS) in 2019:
 2535 Column AL: C emissions due to fire
 2536 Column AM: CH₄ emissions due to fire
 2537 Column AN: N₂O emissions due to fire
 2538 Column AO: C emissions due to disordered logging (CS)
 2539 Column AP: C loss due to fire in unmanaged lands
 2540 Column AQ: C loss due to orderly logging (CSR)
 2541
- 2542 ○ **Step 7:** Calculation of the remaining carbon stocks available after degradation in 2019,
 2543 defining the carbon stocks available for potential degradation in 2020:
 2544 Column AR: aerial C stock t_3
 2545 Column AS: above ground C stock t_3
 2546
- 2547 ○ **Step 8:** Calculation of C, CH₄ and N₂O emissions due to degradation by fire in managed
 2548 forest areas or disordered logging (CS) in 2020:
 2549 Column AT: CO₂ emissions due to fire
 2550 Column AU: CH₄ emissions due to fire
 2551 Column AV: N₂O emissions due to fire
 2552 Column AW: C emissions due to disordered logging (CS)
 2553 Column AX: C loss due to fire in unmanaged lands
 2554 Column AY: C loss due to orderly logging (CSR)
 2555
- 2556 ○ **Step 9:** Calculation of carbon stocks available after degradation processes in 2020,
 2557 defining the carbon stocks available for potential degradation in 2021:
 2558 Column AZ: aerial C stock t_4
 2559 Column BA: above ground C stock t_4
 2560
- 2561 ○ **Step 10:** Calculation of CO₂, CH₄ and N₂O emissions from degradation due to fire in
 2562 managed forest areas or disordered logging (CS) in 2021:
 2563 Column BB: CO₂ emissions due to fire
 2564 Column BC: CH₄ emissions due to fire
 2565 Column BD: N₂O emissions due to fire
 2566 Column BE: C emissions due to disordered logging (CS)
 2567
- 2568 ○ **Step 11:** Through dynamic tables, the sums of GHG emissions were calculated. The
 2569 values obtained in this phase are in tons of C, CH₄ and N₂O.
 2570
- 2571 ○ **Step 12:** Emissions are converted into tones of CO₂ equivalent. These values will be
 2572 used in the final calculation and added to the other outputs, to obtain average net
 2573 emission from the biome.

8.4.3. Secondary vegetation output – Amazon biome

• PHASE 1 – GIS operations

The 1st phase involves several spatial operations using SIG tools, with the aim to consolidate all different secondary vegetation activity data. As result, a spreadsheet was obtained, containing the information presented in **Table 50**. Each line of the spreadsheet represents a group of polygons with the same characteristics, with the exception of the area (hectares). The area represents the sum of the individual polygons. Such aggregation was necessary due to the large amount of data.

Table 50 – Amazon secondary vegetation output main parameters

| Variable name | Description | Source |
|------------------|---|--|
| Biome | Biome classification: Amazon | TerraClass |
| class_2014 | Secondary vegetation class for year 2014 | |
| class_2020 | Secondary vegetation class for year 2020 | |
| phytophysiognomy | Ancient vegetation phytophysiognomies | 4 th GHG National Inventory |
| category | Land use category: Forest (F), Grassland (G), Other Forest Land (OFL) and Dunes (Dun) | |
| area_ha | Polygon area | Own estimates |

• PHASE 2 – Removals calculations

- **Step 1:** Calculation of the total area of natural forest regeneration per year (2014 and 2020)
- **Step 2:** Calculation of C removals by natural forest regeneration per year (2014 and 2020) considering factor of 3,03 tC/ha.yr
- **Step 3:** Conversion of tonnes of C tonnes to CO₂ equivalent
- **Step 4:** Calculation of the average annual removal average rate (tC/yr)
- **Step 5:** Application of the value obtained for each year of the reference period

8.4.4. Net GHG emission – Amazon biome³⁵

- **PHASE 3 – Consolidation of results**

- **Step 1:** Calculation of the annual net GHG emission: sum of gross GHG emissions by deforestation and degradation minus removals by natural forest regeneration in each annual period

8.5. Detailed description for estimating GHG emissions/removals in the Cerrado biome

The operational procedures, based on the methodological approach described in page 56, used to estimate GHG emission due to deforestation and removals from growth of natural forest regeneration in the Cerrado biome are presented in sequence.

8.5.1. Deforestation output – Cerrado biome

- **PHASE 1 – GIS operations**

The 1st phase involves several spatial operations using GIS tools, with the aim to consolidate all different deforestation activity data. As result, a spreadsheet was obtained, containing the information presented in **Table 51**. Each line of the spreadsheet represents a single deforestation polygon.

Table 51 – Cerrado deforestation output main parameters

| Variable name | Description | Unit | Spreadsheet column | Source |
|--------------------------|--|------|--------------------|--|
| fid | | n/a | A | |
| Biome | Biome classification: Cerrado | n/a | B | IBGE, 2019 |
| State | Brazilian political-administrative state | n/a | C | |
| Main_class | REDD+ activity | n/a | D | PRODES |
| Class_name | REDD+ activity/year classification | | E | |
| Year | Mapping year | n/a | F | |
| Image_date | Image date of each polygon | n/a | G | |
| source_inv | Corresponding biome classification in the 4 th GHG National Inventory | n/a | H | 4 th GHG National Inventory |
| phytophysognomies | Ancient vegetation phytophysognomies | n/a | I | |

³⁵ Refer to file “3_Amazon_net_emissions.xlsx”

| Variable name | Description | Unit | Spreadsheet column | Source |
|---------------|-------------------------------|-------|--------------------|------------------|
| Category | Land use category: Forest (F) | n/a | J | |
| rr_cagb | Above ground carbon stock | tC/ha | K | |
| rr_cbgb | Below ground carbon stock | tC/ha | L | |
| rr_cdw | Dead wood carbon stock | tC/ha | M | |
| rr_clitter | Litter carbon stock | tC/ha | N | |
| rr_ctotal | Total carbon stock | tC/ha | O | |
| Area_ha | Polygon area | ha | P | Own calculations |

• PHASE 2 – Emissions calculations

- **Step 1:** Calculation of C and CO₂ due to deforestation:
Column Q: C emissions due to deforestation
Column R: CO₂ emissions due to deforestation
- **Step 2:** Calculation of the mass of fuel available for fire combustion in the “slash and burn” type deforestation
Column S: above ground C stock
- **Step 3:** Calculation of CH₄ and N₂O emissions due to “slash and burn” deforestation:
Column T: CH₄ emissions due to deforestation
Column U: N₂O emissions due to deforestation
- **Step 4:** Through pivot tables, the sum of emissions per year and GHG are calculated. The values obtained at this stage are in tonnes of CO₂, tonnes of CH₄ and tonnes of N₂O.
- **Step 5:** Emissions are converted into tones of CO₂ equivalent. These values will be used in the final calculation and added to the other outputs, to obtain the average net emission for the biome.

8.5.2. Secondary vegetation output – Cerrado biome

• PHASE 1 – Georeferenced operations

The 1st phase involves several “georeferenced operations” using SIG tools, with the aim to consolidate all different deforestation activity data. As result, a spreadsheet was obtained, containing the information presented in **Table 52**. Each line of the spreadsheet represents a group of polygons with the same characteristics, with the exception of the area (hectares). The area represents the sum of the individual polygons. Such aggregation was necessary due to the large amount of data.

Table 52 – Cerrado secondary vegetation output main parameters

| Variable name | Description | Source |
|------------------|---|--|
| Biome | Biome classification: Cerrado | TerraClass |
| class_2018 | Secondary vegetation class for year 2018 | |
| class_2020 | Secondary vegetation class for year 2020 | |
| phytophysiognomy | Ancient vegetation phytophysiognomies | 4 th GHG National Inventory |
| category | Land use category: Forest (F), Grassland (G), Other Forest Land (OFL) and Dunes (Dun) | |
| Area_ha | Polygon area | Own calculations |

PHASE 2 – Emissions calculations

- **Step 1:** Calculation of total area of secondary vegetation per year (2014 and 2020)
- **Step 2:** Calculation of C removals by secondary vegetation per year (2014 and 2020) considering factor of 3,03 tC/ha.yr
- **Step 3:** Conversion of C tones to CO₂ equivalent
- **Step 4:** Calculation of the annual removal average rate (tC/yr)
- **Step 5:** Application of the value obtained for each year of the series

8.5.3. Net GHG emission – Cerrado biome

PHASE 3 – Consolidation of results

- **Step 1:** Calculation of the annual net GHG emission: sum of gross GHG emissions by deforestation minus removals by secondary vegetation in each period
- **Step 2:** Calculation of average net emissions in the period

8.6. Detail description for estimating GHG emissions/removals in the Atlantic Forest, Caatinga, Pampa and Pantanal biomes

PHASE 1 – GIS operations

The 1st phase involves several spatial operations using GIS tools, with the aim to consolidate all different deforestation activity data. As result, a spreadsheet was obtained, containing the information presented in **Table 53**. Each line of the spreadsheet represents a single deforestation polygon.

Table 53 – Atlantic Forest, Caatinga, Pampa and Pantanal biomes deforestation output main parameters

| Variable name | Description | Unit | Spreadsheet column | Source |
|---------------------------|--|-------|--------------------|--|
| fid | | n/a | A | |
| Biome | Biome classification | n/a | B | IBGE, 2019 |
| Main_class | REDD+ activity | n/a | C | PRODES |
| Year | Mapping year | n/a | D | |
| Image_date | Image date of each polygon | n/a | E | |
| source_inv | Corresponding biome classification in the 4 th GHG National Inventory | n/a | F | 4 th GHG National Inventory |
| phytophysiognomies | Ancient vegetation phytophysiognomies | n/a | G | |
| Category | Land use category: Forest (F) | n/a | H | |
| rr_cagb | Above ground carbon stock | tC/ha | I | |
| rr_cbgb | Below ground carbon stock | tC/ha | J | |
| rr_cdw | Dead wood carbon stock | tC/ha | K | |
| rr_clitter | Litter carbon stock | tC/ha | L | |
| rr_ctotal | Total carbon stock | tC/ha | M | |
| Area_ha | Polygon area | ha | N | Own calculations |

- **PHASE 2 – Emissions calculations**

- **Step 1:** Calculation of C and CO₂ due to deforestation:

Column Q: C emissions due to deforestation

Column R: CO₂ emissions due to deforestation

- **Step 2:** Through pivot tables, the sums of emissions per year and GHG are calculated. The values obtained at this stage are in tons of CO₂, tons of CH₄ and tons of N₂O.

- **Step 3:** Emissions are converted into tones of CO₂. These values will be used in the final calculation, added to the other outputs, to obtain average net emission from the biome.

- **PHASE 3 – Consolidation of results**

- **Step 1:** Calculation of the gross CO₂ emissions per period as the sum of individual emissions per polygon

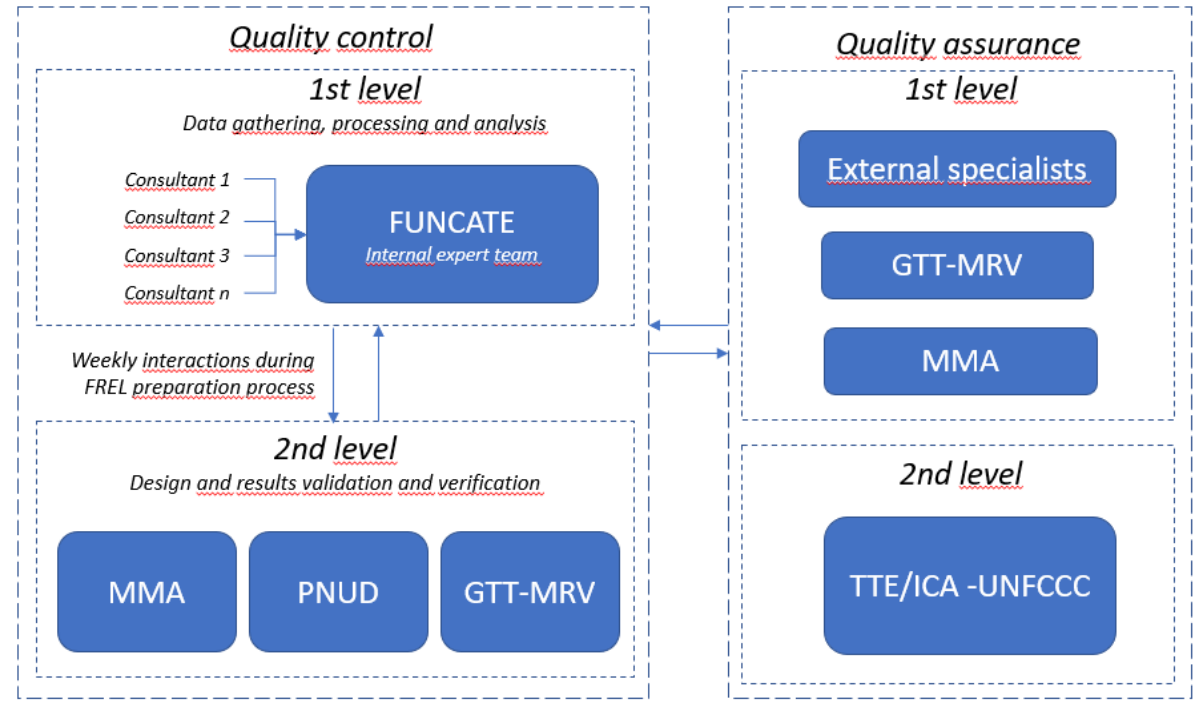

- **Step 2:** Calculation of average gross emissions in the period and biome

8.7. Detail description for estimating the national FREL

- **Step 1:** regrouping the emissions for each biome and year
- **Step 2:** calculation of the net emissions balance per year
- **Step 3:** calculation of the average net emission in the period 2016/2017-2019-/2021, considered as the National FREL

2726 8.8. Quality control and quality assurance procedures

2727
2728 The following figure, summarize the quality control (QC) and quality assurance (QA)
2729 procedures that were adopted and implemented, by different actors, during the elaboration
2730 of Brazil's national FREL proposal. Is worth to recall that INPE's monitoring programs, also
2731 have they own QA/QC procedures, ensuring that activity data used in this submission is highly
2732 accurate.
2733

2734
2735 **Figure 50 –QA and QC procedures adopted/implemented during the elaboration of Brazil's**
2736 **National FREL**

2737
2738 8.8.1. Quality control

2739
2740 Throughout the preparation of Brazil's National FREL, technical QC procedures were
2741 implemented to evaluate and correct (when necessary) the quality of the results, as
2742 recommended by the 2006 IPCC Guidelines.

2743
2744 These procedures were implemented at two different levels (**Figure 50**): at a first level within
2745 FUNCATE expert team directly involved in the preparation of the GHG estimates; and at a
2746 second level within MMA expert team, technical coordinator and selected GTT-MRV
2747 members directly involved in the elaboration of the FREL submission document, but not
2748 directly involved in the calculation of the estimates.

2749
2750 From this perspective, the quality control system has been delineated for (non-exhaustive list
2751 to date):

2752
2753
2754
2755
2756
2757
2758
2759
2760
2761
2762
2763
2764
2765
2766
2767
2768
2769
2770
2771
2772
2773
2774
2775
2776
2777
2778
2779
2780
2781

(i) Routine checks to ensure the integrity, correctness and completeness of all data used in the FREL elaboration:

- Level 1: All data necessary for estimating emissions/removals (i.e., activity data and EF) were subject to completeness checks, to ensure that all necessary data have been gathered. Maps used have undergone integrity assessments (i.e., topological analyses relevant to this type of data), and corrections have been applied when necessary.
- Level 2: All data were examined by the MMA, technical coordinator, and UNDP team.

(ii) Calculation checks:

- Level 1: Calculations were carried out, in parallel, by two different experts to ensure the consistency and accuracy of the results.
- Level 2: All results were examined by the MMA, technical coordinator, and UNDP team.

(iii) Documentation and archiving:

- Level 1: Several reports were produced throughout the project detailing the input data and procedures adopted.
- Level 2: Weekly meetings were held between FUNCATE, MMA and UNDP to discuss and decide on the process, gaps, assumptions, preliminary results, etc. Meetings were recorded.

The main errors and/or gaps identified during the QC procedures, and corrections applied are presented in the following tables.

2782 **Table 54 – Errors and/or gaps identified during the quality control check – Amazon biome**

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|---|--|--|---|---|--|
| Overlap of polygons | Same polygons have different classification in terms of phytophysionomies | Error due to the large amount of information to be assessed | Overlaps can be generated emissions overload | 0,24% of the total area deforested on Forest category | A TerraAmazon tool was used to eliminate polygon overlap in the ancient vegetation map |
| Gaps in the ancient vegetation map | Polygons without information of the forest phytophysionomies and/or category | Gasps may have been created due to differences in the biome's limits | Without the forest phytophysionomies emissions can't be estimated | 1% of the total area deforested | Due to its insignificance, missing area was not considered in the final estimates |

2783
2784 **Table 55 – Errors and/or gaps identified during the quality control check – Cerrado biome**

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|---|--|--|---|--------------------------------------|--|
| Gaps in the ancient vegetation map | Polygons without information of the forest phytophysionomies and/or category | Gasps may have been created due to differences in the biome's limits | Without the forest phytophysionomies emissions can't be estimated | 0.0033% of the total area deforested | Due to its insignificance, missing area was not considered in the final estimates |
| Inconsistencies between carbon stocks included in the shapefile and the ones reported in the 4th National GHG Inventory | Sum of carbon stocks pools in the shapefile differs from values reported in the 4 th National GHG Inventory | Most likely due to human errors when inserting data | Reduction of the estimate accuracy | 3.2% of the total area deforested | Values from the 4 th National GHG Inventory were used, adjusted per biome |

2785
2786 **Table 56 – Errors and/or gaps identified during the quality control check – Atlantic Forest biome**

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|--|--|--|---|-----------------------------------|---|
| Gaps in the ancient vegetation map | Polygons without information of the forest phytophysionomies and/or category | Gasps may have been created due to differences in the biome's limits | Without the forest phytophysionomies emissions can't be estimated | 1.6% of the total area deforested | Due to its insignificance, missing area was not considered in the final estimates |
| Inconsistencies between carbon stocks included in the shapefile and the | Sum of carbon stocks pools in the shapefile differs from values | Most likely due to human errors when inserting data | Reduction of the estimate accuracy | 3.2% of the total area deforested | Values from the 4 th National GHG Inventory |

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|---|--|--|---|-----------------------|--|
| ones reported in the 4th National GHG Inventory | reported in the 4 th National GHG Inventory | | | | were used, adjusted per biome |
| PRODES residue class | PRODES residue class refers to deforestation areas identified after the occurrence. For example, a 2018 residue class, implies that the deforestation has been reported in 2018, but have occurred before 2018 | This class is part of the PRODES Cerrado data transferred to Atlantic Biome. This means this is not an error, is part of the methodology | Deforestation and corresponding emission may have occurred “outside” the reference level period | 0.5% of the emissions | Residue class was not included in the final estimates |
| Unknown forest phytophysognomies | Ancient vegetation map present’s unknown forest phytophysognomies: SNm, SMm, SNs, SNtm and TNm | Most likely due to human errors when inserting data | Reduction of the estimate accuracy | 0.5% of the emissions | Carbon stocks values from the “higher” forest phytophysognomies have been used |

2787

2788

Table 57 – Errors and/or gaps identified during the quality control check – Caatinga biome

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|---|--|---|---|------------------------------------|---|
| Gaps in the ancient vegetation map | Polygons without information of the forest phytophysognomies and/or category | Gaps may have been created due to differences in the biome’s limits | Without the forest phytophysognomies emissions can’t be estimated | 85% of the total area deforested | Forest phytophysognomies were identified (based on information reported in the 4 th National GHG Inventory) and included in the ancient vegetation map |
| Inconsistencies between carbon stocks included in the shapefile and the ones reported in the 4th National GHG Inventory | Sum of carbon stocks pools in the shapefile differs from values reported in the 4 th National GHG Inventory | Most likely due to human errors when inserting data | Reduction of the estimate accuracy | 0,93% of the total area deforested | Values from the 4 th National GHG Inventory were used, adjusted per biome |

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|---|--|--|---|-----------------------|--|
| PRODES residue class | PRODES residue class refers to deforestation areas identified after the occurrence. For example, a 2018 residue class, implies that the deforestation has been reported in 2018, but have occurred before 2018 | This class is part of the PRODES Cerrado data transferred to Atlantic Biome. This means this is not an error, is part of the methodology | Deforestation and corresponding emission may have occurred “outside” the reference level period | 3% of the emissions | Residue class was not included in the final estimates |
| Unknown forest phytophysiologicals | Ancient vegetation map present’s unknown forest phytophysiologicals: SNm, SNs, SNtm, SNts, STNtm, STNts, STs, STts, STtm , TNm, TNs, TNtm, TNts | Most likely due to human errors when inserting data | Reduction of the estimate accuracy | 3.3% of the emissions | Carbon stocks values from the “higher” forest phytophysiologicals have been used |

2789

2790

Table 58 – Errors and/or gaps identified during the quality control check – Pampa biome

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|---|--|--|---|------------------------------------|--|
| Gaps in the ancient vegetation map | Polygons without information of the forest phytophysiologicals and/or category | Gasps may have been created due to differences in the biome’s limits | Without the forest phytophysiologicals emissions can’t be estimated | 0.03% of the total area deforested | Forest phytophysiologicals from the neighbor polygon were used |
| Inconsistencies between carbon stocks included in the shapefile and the ones reported in the 4th National GHG Inventory | Sum of carbon stocks pools in the shapefile differs from values reported in the 4 th National GHG Inventory | Most likely due to human errors when inserting data | Reduction of the estimate accuracy | 10,3% of the total area deforested | Values from the 4 th National GHG Inventory were used, adjusted per biome |
| New forest phytophysiologicals | A new forest phytophysiologicals (Mm) were identified | New forest phytophysiologicals due to new biome’s limits | Reduction of the estimate accuracy | 0.003% of the emissions | Carbon stocks values from other biome (Atlantic forest) have been used |

2791

2792

2793

Table 59 – Errors and/or gaps identified during the quality control check – Pantanal biome

| Error/gap | Description | Possible cause | Impact | Significance | Correction applied |
|---|--|--|---|-------------------------------------|---|
| Gaps in the ancient vegetation map | Polygons without information of the forest phytophysognomies and/or category | Gaps may have been created due to differences in the biome's limits | Without the forest phytophysognomies emissions can't be estimated | 0.04% of the total area deforested | Forest phytophysognomies were identified (based on information reported in the 4 th National GHG Inventory) and included in the ancient vegetation map |
| Inconsistencies between carbon stocks included in the shapefile and the ones reported in the 4th National GHG Inventory | Sum of carbon stocks pools in the shapefile differs from values reported in the 4 th National GHG Inventory | Most likely due to human errors when inserting data | Reduction of the estimate accuracy | 24,86% of the total area deforested | Values from the 4 th National GHG Inventory were used, adjusted per biome |
| PRODES residue class | PRODES residue class refers to deforestation areas identified after the occurrence. For example, a 2018 residue class, implies that the deforestation has been reported in 2018, but have occurred before 2018 | This class is part of the PRODES Cerrado data transferred to Atlantic Biome. This means this is not an error, is part of the methodology | Deforestation and corresponding emission may have occurred "outside" the reference level period | 0.06% of the emissions | Residue class was not included in the final estimates |

2794

8.8.2. Quality assurance

As described in section “The role of the Working Group of Technical Experts on REDD+ for MRV”, all key inputs for the development of this submission have been presented and discussed by the GTT MRV REDD+.

The GTT MRV REDD+ also was instrumental in the process of quality assurance of the results, by performing expert judgment assessment in order to identify potential outliers that could result in under or over estimation.

A draft proposal of the submission (including preliminary results) was presented to the GTT MRV REDD+ and “technical validation processes” happened on October 30, November 1st, and December 12 2022.

As result of the “technical validation process”, is worth to mention that the GTT-MRV considered the data, information and results presented in this FREL submission complete, methodological robust, and representing the most up to set of information available in the country.

Finally, since REDD+ submissions are subject to technical analysis by LULUCF experts from the UNFCCC roster of experts, it can be expected that additional QA procedures will be carried out during the technical analysis.

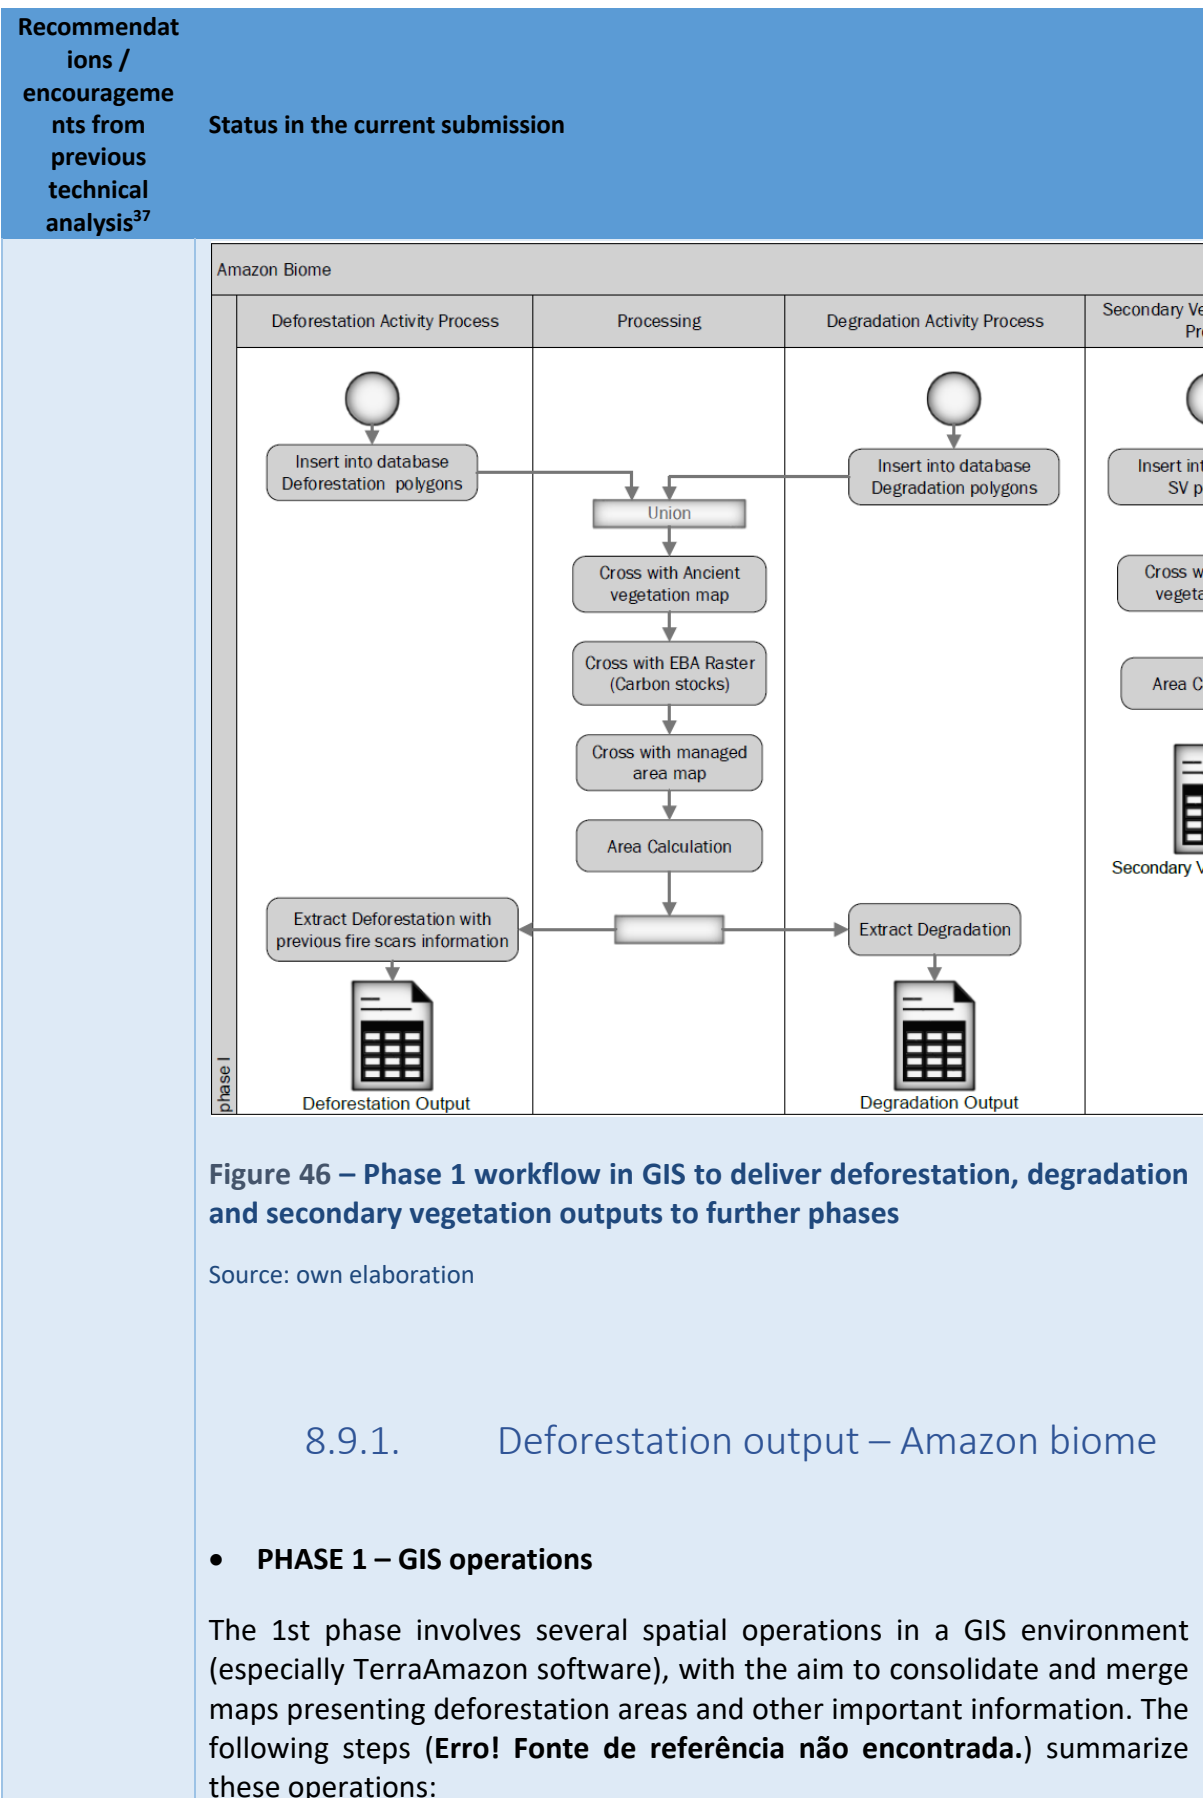

8.9. Status of recommendations/encouragements from previous technical analysis

Table 60 – Status of recommendations/encouragements from previous technical analysis - FREL Amazônia A, B³⁶

| Recommendations / encouragements from previous technical analysis ³⁷ | Status in the current submission |
|--|--|
| Digitalization of deforestation maps: it was noted that estimates of deforestation for the years 1996–1997 are less accurate than the rest of the time series. The AT considers that a better estimation of estimates for the years 1996–1997 may be achieved through digitalization of the deforestation maps | <p>All thematic maps used in this FREL submission were designed in digital format according to the same criteria of extracting information from orbital images, thus avoiding possible inconsistencies and inaccuracies between maps elaborated by different methodologies. It is understood that the 1996 and 1997 maps have no impact on the accuracy of the FREL proposed here, since Brazil have decided for a shorten reference level period (i.e., 5 years), aligned with other international guidance's.</p> <p>In addition, quality control procedures have been implemented to exclude “less accurate AD” – refer to section “The operational procedures, based on the methodological approach described in page 56, used to estimate GHG emissions due to deforestation, forest degradation and removals from secondary vegetation growth in the Amazon biome are detailed below. Overview of phase 1 is presented in Figure 46, where spatial data is assembled and spreadsheets are acquired to next calculation steps.</p> |

³⁶ Available at: https://redd.unfccc.int/files/redd_brazil_frel_final_19nov.pdf

³⁷ Paragraphs 37, 38 and 39 of the “Report of the technical assessment of the proposed forest reference emission level of Brazil submitted in 2014” (FCCC/TAR/2014/BRA) Available at: <https://unfccc.int/resource/docs/2014/tar/bra01.pdf>

Recommendations / encouragements from previous technical analysis³⁷

Status in the current submission

○ **Step 1: Vectorial data gathering and verification (database creation), considering:**

a. PRODES maps presenting polygons of native vegetation conversion increments for the periods 2016-2017, 2017-2018, 2018-2019, 2019-2020 and 2020-2021

b. DETER degradation maps presenting fire scars and selective logging areas

c. Biomes boundaries (**Figure 1**)

d. Ancient native vegetation map (**Figure 9**)

e. Managed areas map

Verifications consists in a routine of procedures to identify topology errors (such as overlaps and gaps) and lack of information.

○ **Step 2:** Spatial operations execution to join step 1 data and then to filter only deforestation polygons (i.e., native vegetation clearing occurring in forest phytophysionomies according to the ancient native vegetation map).

○ **Step 3:** Association of the emission factors (i.e., carbon stocks per unit area) to each deforestation polygon through the extraction of the spatial average value from the EBA raster map (4th National GHG Inventory maps presenting each carbon pool).

○ **Step 4:** Exportation of an electronic spreadsheet containing, for each annual period of the reference period, the deforestation polygons and their corresponding phytophysionomies and associated carbon stocks for above-ground biomass, below-ground biomass, dead wood and litter - **Table 47**.

Table 47 – Outcome of phase 1 “GIS operations” for the Amazon deforestation component, which is the input for next phases.

Figure 48 – Emission results by the year 2017 according to the sources/activities in the Deforestation Outputs

Source: own elaboration

Step 22: Emissions are converted into tones of CO2 equivalent. These values are used in the final calculation, added to the other outputs, to obtain the average net emission for the relevant biome.

Figure 49 presents an example of CO2 eq emissions by REDD+ activity for the biome.

|---|---|
| | <p>Step 3: calculation of the average net emission in the period 2016/2017-2019-/2021, considered as the National FREL</p> <p>Quality control and quality assurance procedures”</p> |
| <p>Continuation of improvement of the carbon map: the AT acknowledges the significant efforts made thus far by Brazil to assess the spatial distribution in carbon densities in the Amazonia biome and commends Brazil for continuing to work on updating and improving the carbon map based on new and improved ground data from its first national forest inventory</p> | <p>Brazil continues to improve the estimates and spatial distribution of carbon stocks in all biomes. These efforts have been mainly conducted within the scope of the LULUCF sector of the National GHG Inventory</p> <p>In addition, updated data/information from the EBA project have been used to estimate the “carbon map”, particularly for the Amazon biome – refer to Box 2. Future additional improvements are expected once the NFI is fully completed and validated.</p> |
| <p>Treatment of emissions from dead wood (i.e. the inclusion of this pool or the provision of more information on the justification of its omission);</p> | <p>Dead wood pool has been included – refer to section “Pools, gases, and activities included in Brazil’s national FREL”</p> |

| Recommendations / encouragements from previous technical analysis ³⁷ | Status in the current submission |
|---|--|
| Treatment of non-CO ₂ gases, to maintain consistency with the GHG inventory included in the national communication | <p>Non-CO₂ gases have been included in the estimates for:</p> <ol style="list-style-type: none"> 1) Deforestation in the Amazon and Cerrado biomes 2) Degradation by forest fires in the Amazon biome <p>Nevertheless, due to current limitations non-CO₂ gases that may occur in other biomes have not yet been included – refer to Box 6</p> |
| In assessing the activities included in the FREL, the AT considers that degradation is a significant activity based on the estimates provided by Brazil. The justification provided by Brazil to omit this activity is that the time series available is too short to allow an adequate understanding of the degradation process. Based on the available information, the AT notes that, so far, there is no evidence of displacement of emissions (i.e., decreased deforestation in the Amazonia | <p>National discussions about "forest degradation" and "deforestation" have been quite exhaustive over the last few years in the context of the GTT-MRV. In this new submission, due to available data, forest degradation was included in the Amazon biome only. The selected drivers of degradation were fires in managed forest land and disordered logging. For the Cerrado biome, it was not possible to take into account degradation due to fire because of lack of activity data and high uncertainties. For other Biomes it was recognized that fires do not play a significant role in forest degradation (see Box 5 and Box 6) and disordered logging, when it occurs, presents low intensity, and its identification in orbital images is not feasible with spatial resolutions currently used by INPE.</p> <p>Regarding the relationship between degradation and deforestation, it should be noted that the process and sequence of degradation was considered for the purposes of calculating emissions in subsequent deforestation. That is, although the relationship has not been thoroughly analyzed, its consequences in terms of reducing carbon stocks for the purposes of calculating emissions associated with deforestation have been taken into account</p> |

| Recommendations / encouragements from previous technical analysis ³⁷ | Status in the current submission |
|---|----------------------------------|
| <p>biome resulting in increasing degradation). In addition, the AT notes that the current exclusion of degradation appears to be conservative in the context of constructing the FREL. Overall, the AT considers better understanding of the relationship between degradation and deforestation as an area for future technical improvement of the FREL. The AT notes that, when emissions from degradation are included in the FREL, Brazil will need to demonstrate how double counting of emissions included under degradation and deforestation is avoided (e.g. for forests that</p> | |

³⁹ Paragraphs 41 and 42 of the “Report of the technical assessment of the proposed forest reference emission level of Brazil submitted in 2018” (FCCC/TAR/2018/BRA). Available at: https://unfccc.int/sites/default/files/resource/tar2018_BRA.pdf

Recommendations / encouragements from previous technical analysis³⁹

Status in the current submission

○ **Step 1: Vectorial data gathering and verification (database creation), considering:**

a. PRODES maps presenting polygons of native vegetation conversion increments for the periods 2016-2017, 2017-2018, 2018-2019, 2019-2020 and 2020-2021

b. DETER degradation maps presenting fire scars and selective logging areas

c. Biomes boundaries (**Figure 1**)

d. Ancient native vegetation map (**Figure 9**)

e. Managed areas map

Verifications consists in a routine of procedures to identify topology errors (such as overlaps and gaps) and lack of information.

○ **Step 2:** Spatial operations execution to join step 1 data and then to filter only deforestation polygons (i.e., native vegetation clearing occurring in forest phytophysionomies according to the ancient native vegetation map).

○ **Step 3:** Association of the emission factors (i.e., carbon stocks per unit area) to each deforestation polygon through the extraction of the spatial average value from the EBA raster map (4th National GHG Inventory maps presenting each carbon pool).

○ **Step 4:** Exportation of an electronic spreadsheet containing, for each annual period of the reference period, the deforestation polygons and their corresponding phytophysionomies and associated carbon stocks for above-ground biomass, below-ground biomass, dead wood and litter - **Table 47**.

Table 47 – Outcome of phase 1 “GIS operations” for the Amazon deforestation component, which is the input for next phases.

Source: own elaboration

Step 22: Emissions are converted into tones of CO2 equivalent. These values are used in the final calculation, added to the other outputs, to obtain the average net emission for the relevant biome.

Figure 49 presents an example of CO2 eq emissions by REDD+ activity for the biome.

8.10.3. Degradation output – Amazon biome

PHASE 1 – GIS operations

The 1st phase involves several “georeferenced operations” using SIG tools, with the aim to consolidate all different degradation activity data. As result, a spreadsheet was obtained, containing the information presented in **Table 49**. Each line of the spreadsheet represents a group of polygons with the same characteristics, with the exception of the area (hectares). The area represents the sum of the individual polygons. Such aggregation was necessary due to the large amount of data.

Table 49 – Amazon degradation output main parameters

| Variable name | Description | Unit | Spreadsheet column | Source |
|------------------|---|------|--------------------|----------------------------|
| Biome | Biome classification: Amazon | n/a | A | IBGE, 2019 |
| Main_class | REDD+ activity classification: “DEGRAD” meaning “degradation” | n/a | B | DETER |
| deter2017 | Degradation classification in corresponding year: - Fire (“burn scar”) - Disordered logging (“CS”) - orderly logging (“CSR”) | n/a | C | |
| deter2018 | | n/a | D | |
| deter2019 | | n/a | E | |
| deter2020 | | n/a | F | |
| deter2021 | | n/a | G | |
| status | | | H | |
| source_inv | Corresponding biome classification in the 4th GHG National Inventory | n/a | I | 4th GHG National Inventory |
| Phytophysiognomy | Ancient vegetation phytophysiognomies | n/a | J | |
| category | Vegetation category: Forest (F) | n/a | K | |
| Managed_land | indicates whether the polygon is situated in a managed area (“t” = true) or not (“f” = falsa) | | L | |

| | Quality control and quality assurance procedures" |
| Provide information on the extent of deforested areas that are detected at the 1 ha threshold but not retrieved later by the PRODES project using a 6.25 ha threshold, with the aim of showing that no significant deforestation is excluded from the FREL | Deforestation have been estimated used a minimum map unit of 1 hectare – refer to section "Estimation of Brazil's national FREL" |
| Provide information on how the EFs were derived for the five vegetation types that were not included in the 22 forest types of the FREL | Information on how EFs were derived for each biome have been included – refer to section "Estimation of Brazil's national FREL" |
| Provide a territorial matrix of the Amazonia biome in the FREL with the distribution considered by the national communication and by the FREL, along with a clear description of | Currently, it is not possible to present a "territorial matrix" since INPE methodology for monitoring deforestation does not include procedures for the identification of land use after deforestation. In other words, it can only be said that the deforestation areas presented here relate to forest conversions (F) to another non-forest land category, as defined as "deforestation", but without a clear definition if the land is Cropland, Grassland, etc. |

| Recommendations / encouragements from previous technical analysis ³⁹ | Status in the current submission |
|---|--|
| any methodological differences | |
| Better explain the difference of 5,573,793.6 ha between the PRODES deforestation increments in the third national communication and in the FREL | <p>The difference is potentially explained by the fact that in PRODES deforestation estimated are included Other Woody Formations (OFL) which are not considered forest phytophysionomies in the 4th National Inventory. There is also the fact that PRODES considers the territory of the Legal Amazon, while the National Inventory considered the Amazon biome, whose limits are different</p> |
| Strengthen the quality control of the submission to eliminate inconsistencies | <p>In this submission all steps taken were supervised both by internal FUNCATE experts, as well as by other external experts with relevant expertise</p> <p>During activity data collection using orbital images, external consultants with specific expertise in each one of the biomes were hired, to guide the team of interpreters, drawing attention to relevant aspects to be considered in the spatial distribution of phytophysionomies and in their phenological dynamics, seeking to minimize possible misunderstandings of interpretation</p> <p>During data processing, considering the large volume and control needs for the elaboration of spreadsheets for future calculations, all work was concentrated in a single expert who interacted with those responsible for the calculations. The occurrence of inconsistencies was promptly reported, and further processing followed</p> <p>After the completion of the calculations, even of those intermediaries, the results were discussed in meetings, with the participation of FUNCATE experts, MMA team, technical coordinator and UNDP team</p> <p>For more information, refer to section “The operational procedures, based on the methodological approach described in page 56, used to estimate GHG emissions due to deforestation, forest degradation and removals from secondary vegetation growth in the Amazon biome are detailed below. Overview of phase 1 is presented in Figure 46, where spatial data is assembled and spreadsheets are acquired to next calculation steps.</p> |

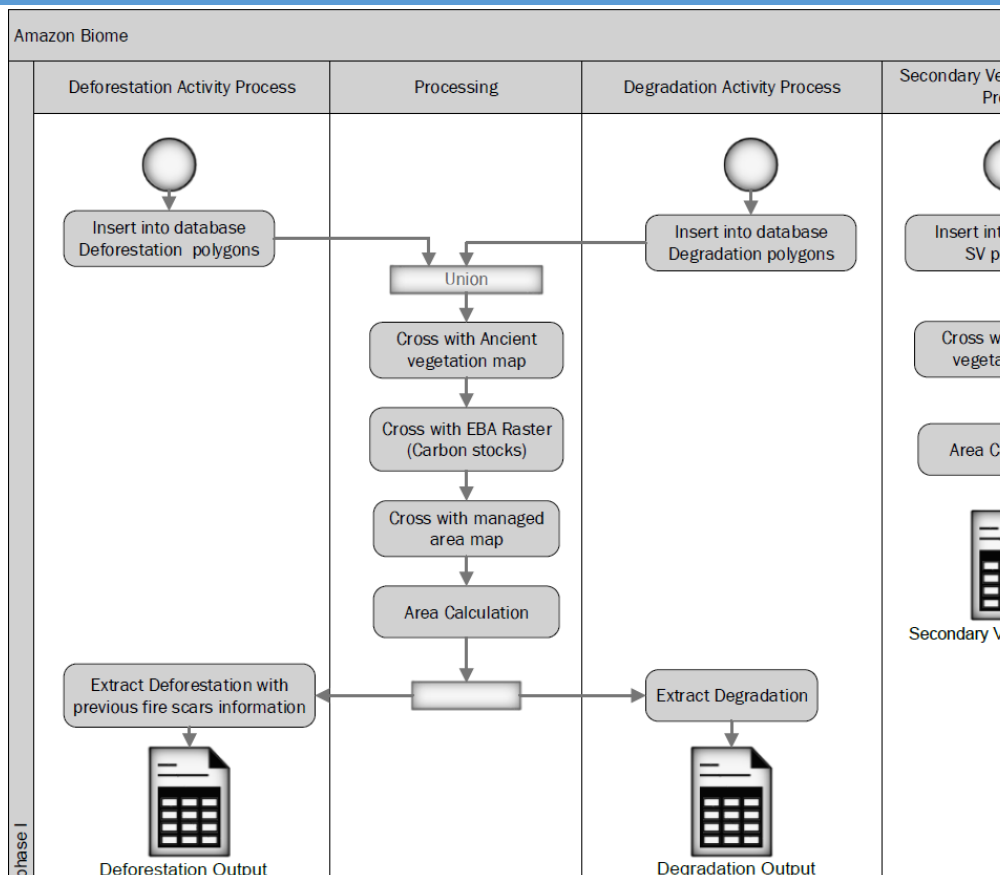

Figure 46 – Phase 1 workflow in GIS to deliver deforestation, degradation and secondary vegetation outputs to further phases

8.13.1. Deforestation output – Amazon biome

- **PHASE 1 – GIS operations**

The 1st phase involves several spatial operations in a GIS environment (especially TerraAmazon software), with the aim to consolidate and merge maps presenting deforestation areas and other important information. The following steps (**Erro! Fonte de referência não encontrada.**) summarize these operations:

Recommendations / encouragements from previous technical analysis³⁹

Status in the current submission

○ **Step 1: Vectorial data gathering and verification (database creation), considering:**

a. PRODES maps presenting polygons of native vegetation conversion increments for the periods 2016-2017, 2017-2018, 2018-2019, 2019-2020 and 2020-2021

b. DETER degradation maps presenting fire scars and selective logging areas

c. Biomes boundaries (**Figure 1**)

d. Ancient native vegetation map (**Figure 9**)

e. Managed areas map

Verifications consists in a routine of procedures to identify topology errors (such as overlaps and gaps) and lack of information.

○ **Step 2:** Spatial operations execution to join step 1 data and then to filter only deforestation polygons (i.e., native vegetation clearing occurring in forest phytophysionomies according to the ancient native vegetation map).

○ **Step 3:** Association of the emission factors (i.e., carbon stocks per unit area) to each deforestation polygon through the extraction of the spatial average value from the EBA raster map (4th National GHG Inventory maps presenting each carbon pool).

○ **Step 4:** Exportation of an electronic spreadsheet containing, for each annual period of the reference period, the deforestation polygons and their corresponding phytophysionomies and associated carbon stocks for above-ground biomass, below-ground biomass, dead wood and litter - **Table 47**.

Table 47 – Outcome of phase 1 “GIS operations” for the Amazon deforestation component, which is the input for next phases.

Column CM: N2O emissions due to deforestation (resulting from slash and burn)

The following table presents a numerical example of the calculations that have been carried out. Is important to note the evolution of total carbon stocks. In green: initial total carbon stocks; in blue: total carbon stocks after degradation events or not; in yellow: emissions due to deforestation whose values are associated with the reduced carbon stocks after previous degradation.

Table 48 – Example of GHG emissions for an area presenting a trajectory that passes through degradation by fire to deforestation

Degradation output – Amazon biome

PHASE 1 – GIS operations

The 1st phase involves several “georeferenced operations” using SIG tools, with the aim to consolidate all different degradation activity data. As result, a spreadsheet was obtained, containing the information presented in **Table 49**. Each line of the spreadsheet represents a group of polygons with the same characteristics, with the exception of the area (hectares). The area represents the sum of the individual polygons. Such aggregation was necessary due to the large amount of data.
