1 INTRODUCTION

1.1 FRL Submission

In accordance with the United Nations Framework Convention on Climate Change (UNFCCC) decisions: 4/CP.15, 1/CP.16, 12/CP.17, 13/CP.19, Cambodia is submitting voluntarily for consideration by the UNFCCC its Second Forest Reference Level (FRL).

In this report, Cambodia provides an overview of the data and methodologies used to voluntarily develop the Second FRL. The information presented is intended to be transparent, complete, consistent, and accurate, and is guided by the most recent IPCC good practice guidance and general guidelines (IPCC, 2003, 2006).

A technical set of experts representing sectoral ministries and national institutions were requested to actively participate in a stepwise and scientific-based construction process of this technical report, with the support of different international organizations and stakeholders present in the country.

The Second FRL is based as much as possible on the criteria, definitions, and assumptions used to build the First FRL submitted by Cambodia in 2017¹. However, several elements have been updated, aiming to:

- increase in transparency, consistency, coherence, and accuracy,
- incorporate newly available information and methodologies, and
- construct the FRL to facilitate the upcoming nesting process.

In this regard, fundamental elements and issues to develop the Second FRL need to be addressed, tested and analyzed to facilitate decision making.

The following elements remain from the definitions and choices used on the First FRL:

- Forest definition: Minimum area of 0.5 ha, a minimum height of 5 m or more, and at least 10 percent canopy cover. Rubber plantations, oil palm plantations, and perennial crops are excluded.
- Pools: above-ground Biomass (AGB) and Below -ground Biomass (BGB) are included, while Litter, Deadwood, and Soil Organic Carbon (SOC) are excluded.
- Gases: CO₂ emissions are included, while CH₄ and N₂O are excluded

On the other hand, the following elements have been updated:

- Reference Period: 2010-2018
- Activity Data approach: Stratified Area Estimator (SAE) approach has been used to estimate area change (AD).
- Emission Factors: Calculation and protocols have been updated, and new data has been integrated.
- Uncertainty analysis is included in the report.

¹ https://redd.unfccc.int/files/camfrrl_may_22_2017.pdf

The Second FRL development follows the Modalities and Submission Guidelines described by the UNFCCC (COP, 2013)

1.2 Objectives for developing the Second National FRL.

The first objective of the submission of the Second FRL is to obtain and receive payments for results from Cambodia's REDD+ program implementation.

The second objective is to provide a transparent, more accurate, complete and consistent estimation of the historical emissions from deforestation across various stakeholders. This FRL uses the most updated data and methods available after the submission of the First FRL.

1.3 FRL Modalities

The FRL expressed in tons of carbon dioxide equivalent per year (tCO₂eq/year) is a benchmark for assessing each country's performance in implementing the following activities:

- Reducing emissions from deforestation;
- Reducing emissions from forest degradation;
- Conservation of forest carbon stocks;
- Sustainable management of forests;
- Enhancement of forest carbon stocks.

The FRL shall be established, maintaining consistency with anthropogenic forest-related greenhouse gas emissions by sources and removals by sinks as contained in the national greenhouse gas inventories.

Parties are invited to submit information and rationale on the development of their FRL, including details of national circumstances and, if adjusted, includes details on how the national circumstances were considered.

A stepwise approach may be useful, enabling Parties to improve the FRL by incorporating better data, improved methodologies, and, where appropriate, additional pools.

Parties should update a FRL periodically as appropriate, taking into account new knowledge, new trends and any modification of scope and methodologies.

1.3.1 FRL Submission Guidelines

Submission of FRL should include information that is transparent, complete, consistent with guidance agreed by the Conference of the Parties (COP), and accurate for allowing a technical assessment of the data, methodologies, and procedures used in the construction of a FRL. The information provided should be guided by the most recent IPCC guidance and guidelines, as appropriate, and include:

- a) Information that was used, including historical data, comprehensively and transparently;
- b) Transparent, complete, consistent and accurate information, including methodological information, used at the time of construction of FRL, including, among other things, as appropriate, a description of data sets, approaches, methods, models and assumptions used,

specifications of relevant policies and plans, and descriptions of changes from previously submitted information;

- c) Pools and gases, and activities which have been included and the reasons for omitting a pool and/or activity from the construction of FRL, noting that significant pools and/or activities should not be excluded;
- d) The definition of forest used, if appropriate, in case there is a difference with the definition used in the national GHG Inventory or in reporting to other international organizations, an explanation of why and how the definition used was chosen.

1.4 CAMBODIA'S FOREST SECTOR

Cambodia covers a total area of 181,607 km². Cambodia is categorized as a Least Developed, Low-Income country. Relative peace and stability over the past decade have brought steady economic growth, averaging between 7 and 10 percent since 1998, leading to substantial reductions in poverty, but also increased pressure on Cambodia's natural resources. Cambodia was able to maintain a relatively high forest cover, with one of the highest levels of forest cover in Southeast Asia. While the current forest cover is still relatively high, Cambodia lost a considerable amount of forest over the last two decades, and the pace of land use and forest conversion has seen acceleration.

1.4.1 Forest Governance

Cambodia's forest area is governed by three institutions: Forestry Administration (FA) of the Ministry of Agriculture, Forestry and Fisheries, Fisheries Administration (FiA) of the Ministry of Agriculture, Forestry and Fisheries (MAFF), General Directorate of Administration for Nature Conservation and Protection (GDANCP) of the Ministry of Environment (MoE).

FA is the government authority under MAFF, in managing forest and forest resources of the Permanent Forest Estate (PFE), which comprises naturally growing and planted state forest resources, and is subdivided into the Permanent Forest Reserve (PFR) and Private Forest. The PFR is composed of Production Forest, Protection Forest, and Conversion Forestland. Private Forests shall be maintained by owners with an interesting right to manage, develop and harvest, use, sell, and distribute the product by themselves (Forestry Law 2002).

The policy objectives of the forestry sector under Permanent Forest Estate (PFE) are synthesized into an overarching strategic framework set out in the National Forest Programme 2010-2029, which defines the policy and implementation strategies for the sustainable management of the nation's forestry sector under a series of programmes, including (a) forest demarcation, classification and registration; (b) Conservation and Development of Forest Resource and biodiversity; (c) forest law enforcement and governance; (d) community forestry programme; (e) capacity and research development; and (f) sustainable forest financing.

Forest resources within Protected Areas (PA) are under the jurisdictional management and regulatory authority of the General Directorate of Administration for Nature Conservation and Protection (GDANCP) of the Ministry of Environment (MoE) under the 2008 Protected Areas Law. Cambodia's 65 protected areas and biodiversity corridors, about 7.2 million ha or 40% of total land area. The National Protected Areas Strategic Management Plan (NPASMP) 2016-2030 outlines the implementation framework for

achieving its vision of effective, efficient, and equitable management of the national protected area system in Cambodia.

Under the 2006 Fisheries Law, inundated forests and mangroves, areas outside of PAs, are managed and regulated by the Fisheries Administration (FiA), set out in the Strategic Planning Framework for Fisheries 2010-2019.

Government policies related to climate change adaptation and mitigation include the National Climate Change Strategic Plan 2014-2023, National Strategic Plan on Green Growth Development 2013-2030, and the White Paper on Land Policy, enacted in 2015, which seeks to harmonize cross-sectoral land-use policy to ensure sustainability. In addition, a law on Environmental Impact Assessment and an Environmental Code has been developed. The National Council for Sustainable Development (NCSDD) is to spearhead the harmonization of Cambodia's sustainable development efforts. These various efforts by the RGC are expected to support reducing emissions from the forestry sector through improved governance, inter-ministerial coordination and coherence of land use policy.

Specifically for REDD+, several institutions and mechanisms have been established to streamline REDD+ in government policy and pave the way for the implementation of activities. The REDD+ Taskforce and Taskforce Secretariat were established in 2012. Several technical teams have been created to oversee day-to-day operations, and key components, including the NRS, SIS, and NFMS are being developed. Participation by all major stakeholders, including local communities, indigenous groups, donors and civil society groups have been ensured.

1.4.2 Forest Communities and Women

Forests are of vital importance to Cambodia and many rural communities rely on them for their livelihoods. About 41% of rural households in Cambodia obtain from 20% to 50% of their total livelihood value from forest use, while about 15% of the rural households obtain more than half of their total livelihoods directly from forest use. Women's harvesting is central to maintaining family livelihoods through the utilization of forest resources. Around 80% of rural women collect non-timber forest products (NTFPs) for household consumption and sale. In forest management, women play an important role by engaging in a variety of activities such as patrolling, conducting forest inventory, and collecting NTFPs. Access to and use of forest resources and knowledge is often differentiated by gender².

Despite the vital role of forests in human wellbeing, the country suffers from shortfalls in policy, governance and resources which hinders good forest management. In addition, current gender inequalities in the country exist which results in women being minimally engaged in decision-making processes related to forest management, and their representation in forest management institutions remains low. Available information suggests that they also have less access to information, education, and training opportunities than men, especially on the withdrawal and use of, and dissemination on the conservation and protection of natural resources and environment³.

² Mainstreaming Gender into Cambodia's REDD+ Action and Investment Plan WOCAN 2019

³ Mainstreaming Gender into Cambodia's REDD+ Action and Investment Plan WOCAN 2019

1.4.3 Climate Change and the Nationally Determined Contribution (NDC)

According to indices of vulnerability and readiness for climate change, Cambodia is one of the most at-risk countries globally, specifically its reliance on rice and on inland fisheries⁴, and the threats to the population that rely on these activities from flooding and drought.

Cambodia is considered one of the 10 countries most vulnerable to climate change and one of the three in Asia⁵. Based on the Notre Dame Global Adaptation Index (ND-GAIN) model of vulnerability⁶ Cambodia is ranked 134 (out of 181), and of even higher concern is that for 'readiness', i.e., its 'ability to leverage investments and convert them to adaptation action'⁷, it is ranked 141 in the world (of 191 countries).

The RGC recognises challenges posed through global climate change related impacts and has actively included the prioritization of action on climate change in its national policies and programmes.

As a Least-Developed Country (LDC) and highly vulnerable to climate change, Cambodia understood the urgency to fight against the impacts from climate change. Thus, the country submitted its Nationally Determined Contribution⁸ (NDC) on the 6th of February 2017, and the updated version in December 2020, which is confident that it will contribute to addressing climate issues.

Cambodian's vulnerability is focused on 5 specific areas: agriculture, infrastructure, forestry, human health and coastal zones. NDC 'actions' comply with the REDD+ activities which are mentioned in the NDC document. Key sectors for mitigation actions are energy production, manufacturing industries, transport, waste and renewable energy for irrigation and solar lamps, which shows the importance of the REDD+ process to not only address the forestry sector.

The revised version of the NDC states that the contribution from the Forestry and Other Land Use (FOLU) sector is mainly based on '**reducing the historic emissions from forest sector by half in 2030**', which is also in accordance with the national forest policies and strategies of the National Protected Areas Strategic Management Plan⁹ 2017-2031 (NPASMP) and the Production Forest Strategic Plan 2018-2032 (PFSP). For Cambodia to achieve this ambitious NDC target, an Action and Investment Plan (AIP) of the NRS was set to (i) reduce deforestation and (ii) increase forest cover, in the framework of the revised NDCs.

In Cambodia, as elsewhere, forests and agriculture are intrinsically linked to climate change. Forests are converted to agriculture, contributing to climate change through the release of vast amounts of greenhouse gases stored in the trees and forest soil. At the same time, millions of Cambodians rely on these same forests for a significant portion of their household consumption and income, especially in (increasing) years where drought or floods impact on farming and fishing¹⁰.

⁴http://sdwebx.worldbank.org/climateportal/countryprofile/doc/GFDRRCountryProfiles/wb_gfdr climate change country profile for KHM.pdf

⁵ <https://www.voanews.com/a/changing-climate-has-major-impacts-for-under-prepared-cambodia/3075404.html>

⁶ <https://gain-new.crc.nd.edu/ranking/vulnerability> - Vulnerability measures a country's exposure, sensitivity and ability to adapt to the negative impact of climate change. ND-GAIN measures the overall vulnerability by considering vulnerability in six life-supporting sectors – food, water, health, ecosystem service, human habitat and infrastructure.

⁷ <https://gain-new.crc.nd.edu/ranking/readiness> - economic readiness, governance readiness and social readiness

⁸ <https://www4.unfccc.int/sites/NDCTest/Pages/Party.aspx?party=KHM>

⁹ Previously the National Forestry Plan (2010 – 2029) was effective but since jurisdictional reform over the forestry sector in 2016 all forest has been included in protected areas; therefore, NFP policies and strategies are now included/amended into the NPASMP and PFSP.

¹⁰ <http://www.kh.undp.org/content/dam/cambodia/docs/HDR/2011CHDRClimateChangeandForestry.pdf>

If forests in Cambodia are not urgently protected, and degraded forests are not managed for recovery *'loss of productive forests, as well as biodiversity, will lead to loss of income or livelihood options for forest-dependent communities'*¹¹. This situation will only get worse as the effects of climate change manifest themselves in the coming decades.

While large areas of Cambodia's 9 million ha of forest are protected under Cambodian laws and regulations, Cambodia needs to enhance law enforcement and protection of forest resources to reduce the forest loss. The RGC has approved a long vision for forestry sector governance by reducing GHG emissions from the forestry sector down to Zero percent by 2040. To achieve this vision, some policies have taken place under the national REDD+ mechanism. Besides, the participation of local communities, indigenous groups and the private sector in the implementation of REDD+ policies and measures is fundamental to promote sustainable activities in the AFOLU sector.

Two Ministries are responsible for forests in Cambodia, MAFF and MoE. Due to its mandate over protected areas, the MoE is the principal agency for forest management and conservation, and responsible for approximately 74% of all land area under forest, which, by 2020, is distributed in 65 protected areas and three biodiversity corridors (around 40% of Cambodia's land area).

Therefore, the RGC is firmly committed to forest conservation and has identified REDD+ as a mechanism to mitigate *'impacts of climate change in agriculture, forestry and related sectors'*. Moreover, the RGC has a *'clear vision that REDD+ is the national mechanism that provides an opportunity to support the sustainable management of forest resources in the country'*¹².

Agricultural development is seen as a pillar of Cambodia's National Development; MAFF is responsible for large areas of the country which are significant, in terms of FOLU, for REDD+, and, therefore, if the goal of the NRS to *'reduce deforestation and forest degradation while promoting sustainable management, conservation of natural resources and contribute to poverty alleviation'* is to be met, MoE and MAFF need to work in close partnership to ensure a successful REDD+ outcome under sustainable national development.

1.5 The REDD+ Process

The RGC recognises that deforestation and forest degradation are significant sources of greenhouse gas emissions both nationally and regionally. As an active Party to the UNFCCC, Cambodia fully supports actions to reduce emissions and, as such, wishes to implement more climate-friendly sustainable management of its remaining natural resources, particularly in relation to forest conservation and protection of biodiversity.

The RGC has been a strong supporter of the adoption of REDD+ and has started its REDD+ Readiness process in 2008; two Verified Carbon Standard¹³ (VCS) projects were established in the same year. In 2010, the National REDD+ Roadmap was finalised and a National REDD+ Programme was established in 2012, leading to stakeholder engagement, capacity building and development of institutional arrangements¹⁴.

¹¹ Climate Change and Forestry: Human Development Report (MoE/UNDP 2011).

¹² His Excellency, Prime Minister Hun Sen, 2017 in the National REDD+ Strategy 2017 - 2026

¹³ VCS was previously 'Voluntary Carbon Standard' and changed to 'Verified'

¹⁴ RGC - National REDD+ Strategy 2017 - 2026

As a result, the RGC has developed the National REDD+ Strategy (NRS) and has met the other requirements of the Warsaw Framework for REDD+.

- a. **National REDD+ Strategy**¹⁵ (NRS): In 2017, the RGC endorsed its NRS to set vision, strategies, and key actions to operationalize REDD+ mechanism in Cambodia. The NRS primarily builds upon three national policy frameworks that guide forest management: (i) the Production Forests Strategic Plan (2018-2032), (ii) the National Protected Areas Strategic Management Plan (2017-2030) and (iii) the Strategic Planning Framework for Fisheries (2010-2019). The RGC has also finalized the **Action & Investment Plan** (AIP)¹⁶ for the implementation of the NRS. While ensuring a *gender-responsive*¹⁷ approach, the AIP sets up the *Policies & Measures* as well as the *Implementation Framework* and *Financial Plan* needed to achieve REDD+ objectives.
- b. **Drivers of Forest Change**: There have been various studies that investigated the drivers of deforestation in Cambodia.¹⁸ Those studies reflected the main drivers of deforestation in the country, which has broadly been divided into two main types. On one hand, large scale conversion of forest to industrial croplands (Paddy fields, rubber plantations and annual croplands) and infrastructure development (roads, hydropower dam construction), related economic and planning. On the other hand, unregulated logging and conversion of forestland to other land uses, related to underlying socioeconomic and demography drivers, such as poverty, low employment, and a high rural population. These studies had complemented the formulation of NRS and AIP.
- c. **First Forest Reference Level**¹⁹: the RGC has submitted its first national FRL (for the 2006-2014 reference period) in 2017, and is in the process of the FRL revision (for the 2010-2018 reference period) to be submitted in 2021.
- d. **National Forest Monitoring System**²⁰ (NFMS): Cambodia has launched its NFMS in 2017 to monitor REDD+ activities and is continuously working to improve methodologies used for *Emission Factors* (i.e., data on forest carbon stocks) and *Activity Data* (i.e., data on forest cover change) estimation.
- e. **Safeguards Information System** (SIS): the RGC has submitted to the UNFCCC its first *Summary of Information*²¹ on how Cancun Safeguards will be addressed and respected during the REDD+ implementation.

1.5.1 The Nested System

The RGC has acknowledged the need for clear rules regarding the way actors interested in forest carbon finance operate, engage with, and report to the government. Therefore, to maximize opportunities for forests and people and to overcome the challenges in the AFOLU sector, the nested system aims to i) Enable Cambodia to participate in mechanisms/opportunities as framed by the Article 6 of the Paris Agreement, through fair rules, clear systems and transparency; ii) Enable multiple sources of finance to support forest and climate goals of Cambodia, including private sector finance and participation in voluntary carbon markets; iii) Supplement government capacity to implement the NRS through support for site-based activities; iv) Drive projects to areas of higher risk and promote equity among them; v)

¹⁹ https://redd.unfccc.int/files/camfrl_may_22_2017.pdf

²⁰ www.cambodia-nfms.org

²¹ https://redd.unfccc.int/files/6_cambodia_1st_summary_of_information_on_safeguards-final-oct-2019.pdf

Promote alignment in how projects and the national government measure GHG performance; and vi) Support Cambodia's NDC achievement and prevent the double counting of ERs.

Since the Nested system is closely related to the FRL, the RTS is designing an allocation method of its Second FRL. This allocation scheme allows for jurisdictional REDD+ efforts (national or subnational) to integrate with smaller (project scale) REDD+ activities while generating RBPs at the jurisdictional scale. ERs will be measured and accounted for at multiple scales including national level – where targets are set under the NDC, sub-national level, i.e. Provinces that can set their baselines and measure performance against this (and make sales of ERs) and local levels including projects and communities (also able to develop baselines, measure performance and generate and sell ER credits).

1.6 CONSISTENCY WITH NATIONAL GHG REPORTING

The National GHG Inventory compilation cycle and the preparation of the Second FRL of Cambodia do not precisely match the reporting schedules. Therefore, the information sources and data used to estimate emissions in both reports, in several cases, are not identical. The National GHG Inventory included in the First BUR and Second National Communication of Cambodia was developed in early 2019, using the data and information of the first FRL. **Thus, consistency between reports has a transition period.** The GHG inventory, included in the First BUR of Cambodia, is totally consistent with the First FRL of the country. All the updates, improvements and methodological changes applied in the Second FRL (built-in 2020) are going to be used in the next GHG Inventory cycle.

It is important to highlight that the MRV technical team responsible for the elaboration of the Second FRL, is also responsible for the elaboration of the GHG Inventory in the LULUCF sector. Thus, it ensures consistency between both national reports, FRL and GHG inventories.

2 FOREST DEFINITION, SCOPE AND REFERENCE PERIOD

2.1 Forest Definition

The forest definition adopted by Cambodia for REDD+ follows the National Forest Programme definition for forest and is consistent with the FAO FRA definition but differs in the fact that rubber plantations, oil palm plantations and perennial crops are not reported as forests.

To implement the Cambodia REDD+ programme, the forest definition has been re-defined as follows:

Forest under the REDD+ programme refers to a unit of an ecosystem in the form of wetland and dry land covered by natural or planted vegetation a height of at least 5 meters on an area of at least 0.5 hectares, and canopy crown cover of more than 10%. Areas also included in the REDD+ programme are forest regrowth and areas under afforestation or reforestation. Rubber, oil palm plantations and perennial crops are excluded from this definition (RGC, 2016).

It is important to clarify that for the Forest Reference Level and for the implementation of REDD+ activities, the practical interpretation of the Forest Definition of Cambodia targets forest with trees **with the potential to reach 5 meters height**, on an area of at least 0.5 hectares, and canopy crown cover of more than 10%.

To complement the forest definition, Annex 2 includes a description of the interpretation of the land use classification system.

2.2 Activities, Pools and Gases

The Cambodia Second FRL includes the REDD+ activities “reduce emission from deforestation” (forest land converted to other land types).

Cambodia defines deforestation as forest land converted to other land use categories due to loss of tree cover through various anthropogenic activities. Post deforestation carbon stocks are assumed to be zero; this assumption is made in absence of reliable estimates of remaining biomass stock in newly deforested areas other land uses (or non-forest).

Following the principles of a stepwise approach, Cambodia has a plan to include an estimate of carbon-stock in the areas under post-deforestation in the next FRL and GHG inventories. Cambodia has already started discussions with stakeholders on possible mechanisms to address the carbon stock in deforested areas, and there is a plan to improve the AD for non-forest, including agriculture land and other land use.

The four other the REDD+ activities, “reduce emission from forest degradation”, “enhancements of forest carbon stock”, “forest conservation”, and “sustainable forest management” are excluded from this submission. Until now, Cambodia has not developed or applied methods to accurately estimate emissions or removal related to the excluded activities.

The original Second FRL submission included a removal estimation form “enhancements of forest carbon stock”. However, during the FRL Technical Assessment (TA) Process, the methodology and emission factor

used for the calculation were identified as a weakness due to the lack of alignment with the IPCC guidelines.

To address this issue, Cambodia conducted an internal analysis to gather a National Decision, considering Paragraph 2(c) of the annex to decision 13/CP.19, describing the scope of the TA, notes that the AT is to assess “The extent to which the information provided was transparent, complete²², consistent and accurate”.

In fact, the most pertinent issues related to estimate removals from *Enhancement of Forest Carbon Stock* in the original FRL Submission were:

1. Low accuracy of AD for the “enhancements of forest carbon stock”:
 - a. The map accuracy for the three different periods was extremely low: 1% for 2011-2014 and 0% for the periods 2015-2016 and 2017-2018.
 - b. The Confidence Interval (%) for reference data was extremely wider: 94.4% for the period 2011-2014, 165% for 2015-2016 and 141% for 2017-2018. Therefore, a high combined uncertainty for this activity (100.9%).
2. Limited information to improve the emission factors associated with “enhancements of forest carbon stock”:
 - a. Currently, data and/or information to create a national growth rate for the areas converted from other land uses to the forest is not adequate to generate reliable estimates.
 - b. The monitoring tool for the measurement of enhancement is currently under development and is expected to complete before the next national reports.

Inclusion of enhancement activity would lead to a compromise in accuracy of estimates. Cambodia, therefore, has decided to exclude the REDD+ activity on “Enhancements of Forest Carbon Stock” in this Modified Second FRL Submission.

Besides, as explained during the TA process, a stepwise approach, following the paragraph 10 of decision 12/CP.17, has been considered by Cambodia to address this issue in the next FRL. It is in the interest of Cambodia to include this REDD+ activity and establish a robust monitoring of the areas under reforestation, afforestation and forest restoration interventions.

Out of five carbon pools, as described per IPCC guidelines (IPCC, 2006), two pools, above-ground biomass, and below-ground biomass are included for the Second FRL of Cambodia. Litter, deadwood, and soil organic carbon are excluded from the estimation due to the lack of reliable data.

Regarding the gases included, only CO₂ is included because in Cambodia. CH₄ and N₂O emissions from land use and land use change are minor in the FOLU sector, and the available information is constrained.

2.3 Reference Period

The UNFCCC Decision 12/CP.17 set that FRLs shall be established, taking into account historical data. Thus, the reference period will be determined by the availability and reliability of historical data.

²² Complete here means the provision of information that allows for the reconstruction of the FREL/FRL

However, the UNFCCC does not provide further criteria that countries should consider establishing the reference period, such as the length, or the number of years from the end of the reference period to the submission date. A relatively long period would better capture historical emission patterns or trends. However, overstretching the reference period may result in the inclusion of emission trends that are not representative of expected future emissions and, therefore, may not provide a reasonable basis for the FRL construction (FAO, 2019).

In addition, the land use change maps prior to 2010 were developed using a moderate spatial resolution imagery due to the lack of satellite images that might have impacted the quality of the final change map.

Further, considering the current and emerging recommendations from various initiatives and standards, reference periods exceeding over a 10-year and under a 5-year might not be a representative historical period to investigate the deforestation trends.

In this regard, the agreed **reference period to the FRL updates covers the period from 2011 to 2018**.

3 ACTIVITY DATA

To estimate the Activity Data (AD), methods used by various reporting countries are typically divided into three broad groups: i) pixel counts method from wall-to-wall change maps, ii) areas from stratified samples using wall-to-wall maps as described by Olofsson (2014), iii) areas from systematic sampling (FAO, 2016). Since 2016, the Stratified Area Estimator (SAE) method is reaching more relevance, being the most used method in the years 2018 and 2019. Systematic sampling is also being used more often by countries (Figure 1).

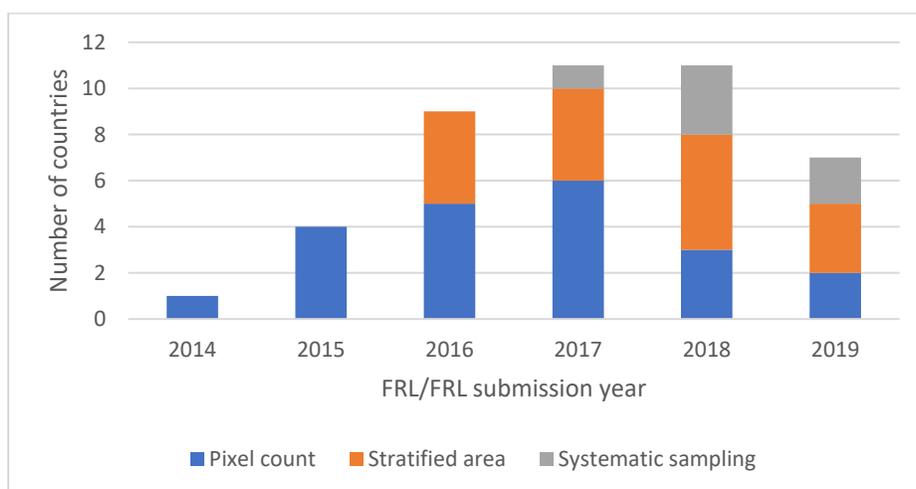

Figure 1. Methods used to assess deforestation in FRL submitted to the UNFCCC. Source: FAO, 2019.

The main reasons for the increased adoption of sampling-based methods are:

1. Confusion or error matrices and map accuracy from **pixel count** methods do not produce the information necessary to construct confidence intervals. Therefore, pixel count methods do not

assure that estimates are “neither over- nor under-estimates” or that “uncertainties are reduced as far as practicable” as required by IPCC definition of good practice (FAO, 2016).

2. Mapping approaches are not well developed because i) wall-to-wall land use/cover change maps do not exist in the country, ii) Historical FCC maps were commonly based on land use/cover maps from different years, which were developed using different methodologies or land classifications, iii) accuracy of the land use/cover change maps is low (FAO, 2019). Besides, sample-based methods can provide more accurate estimates for multiple land use change categories.

The information resources available together with the capabilities to integrate existing data and to provide uncertainty information were decisive for the MRV team to define the integration of the SAE approach to estimate AD within the development of the Second FRL of Cambodia.

The SAE method compares map data with higher quality data collected through a sample-based approach or reference data. As a result, the country obtains accuracy measures and adjusted area estimates for each map category. This process is broken down into four major components: (i) a map to stratify the classes, (ii) the sampling design (iii) the responsive design, and (iv) the analysis (FAO, 2016).

The primary information sources to estimate AD at the national level in Cambodia are the forest cover change (FCC) maps and a dataset of sampling plots used as the reference data.

3.1 FOREST COVER CHANGE MAPS

The FCC Maps are based on the estimation of changes from the land use maps developed by the Royal Government of Cambodia for the years 2010, 2014, 2016, and 2018.

The land use maps are wall-to-wall maps for the whole country using available satellite images (SPOT, Landsat, and Sentinel 2). Each of those maps was classified using the same stratification system (Table 1).

The Land cover maps of 2010 and 2014 are the same presented in the First FRL. For the year 2016 and the year 2018 Land Cover Maps, Cambodia followed the same methodology described in the Annex 3 of the First Forest Reference Level²³, obtaining land cover maps with the same map classes at a minimum mapping unit of 5 Ha.

To develop the Forest Cover Change (FCC) maps, which record any class change between two times, the land cover class of each segment in the initial map is compared with the corresponding segment of the following map. FCC of each period was quantified using a GIS technique for geo-processing and logical functions. The geoprocessing tools used for the detection of land use change are intersection, union, dissolve, and elimination of segments. The statistical tabulation of the land use change was then utilized with the histograms of change.

For the FCC maps periods 2011-2014 (Figure 3), 2015-2016 (Figure 4) and 2017-2018 (Figure 5), the MRV team followed the procedure explained in Figure 2 (T.A. BUR, 2020).

3.2 REFERENCE DATA

During the first quarter of 2019, the MRV team effectuated a campaign to collect reference data, called Mapathon. The purpose of the mapathon was to understand the drivers of deforestation at different spatial scales. Besides, the MRV team adapted this dataset to estimate the accuracy and uncertainty of the FCC Maps.

The reference data was generated from the visual and spectral interpretation of land use for each year, throughout the period 2011-2018. The information was collected in a central database, where each sample plot represents a 0.5 ha. The MRV team use Collect Earth and Google Earth Engine to integrate multitemporal high-resolution image, together with the time-series of each sample based on Landsat

3.2.1 Sampling Design

The sampling design was based on a systematic grid with some densification areas to better describe the drivers of land cover change. Since the deforestation in the period 2011-2014 was much higher than in the subsequent periods, the original grid was only densified around the forest area change of the periods 2015-2016 and 2017-2018.

The total plots collected were 8,917. The protocol for selecting the plots was based on the following systematic samplings:

- **NFI Grid:** A regular 6x6 km grid designed for the implementation of the National Forest Inventory. After Quality Control, 4,921 plots were available.
- **DEF14-16 Grid:** An intensified sampling grid in a 4 km buffer from deforested areas identified in the 2015-2016 FCC Map. After Quality Control, 1,474 plots were available.
- **DEF16-18 Grid:** An intensified sampling grid within deforested areas identified in the 2017-2018 FCC Map. After Quality Control, 2,522 plots were available.

The Figure 6 is represented the area covered by each of the sampling and Figure 7 represents the location of each plot by sampling.

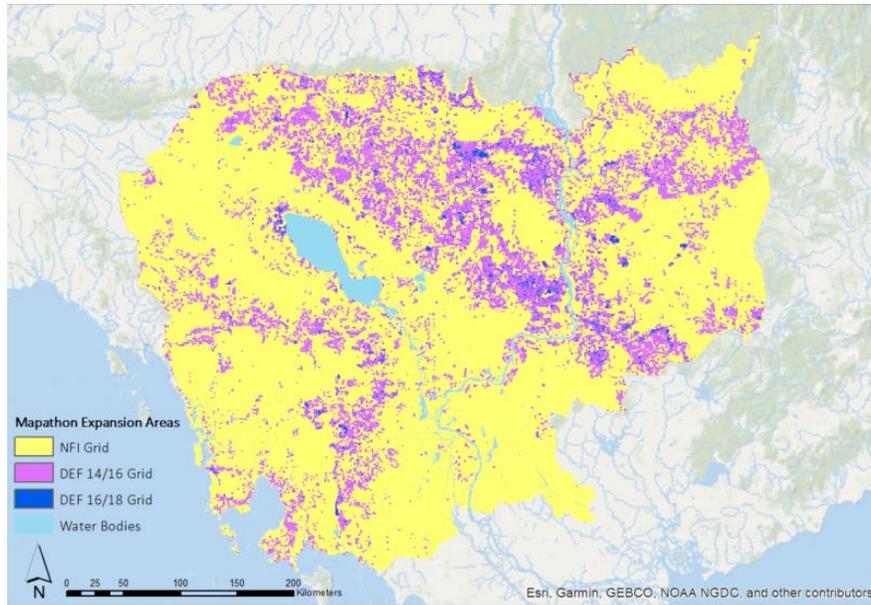

Figure 6. Expansion area by sampling grid. Each color represent the area covered by each of the GRIDS

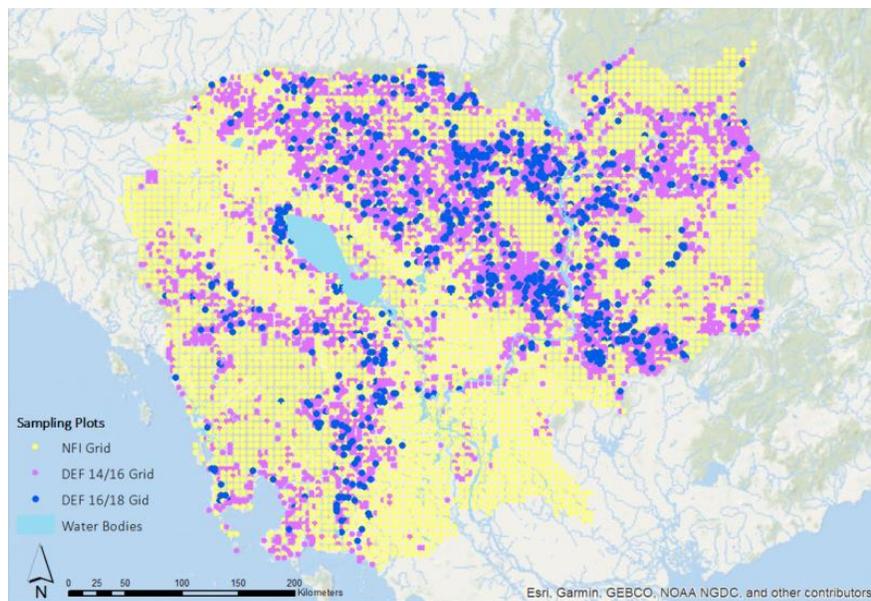

Figure 7. Plots by sampling grid. Each point represents a plot; the color indicates the corresponding GRID.

3.2.2 Response Design

The data collection was conducted by a group of 20 interpreters from the Ministry of Environment (MoE), Ministry of Agriculture (MAFF), Forestry Administration (FA), Fishery Administration (FiA), Royal University of Phnom Penh, SERVIR Mekong, FAO and UNDP.

The survey to collect the land use information of each plot from 2005 to 2019 (Figure 8) was designed in Collect Earth.

Collect earth was synchronized with Earth Engine and with the tree canopy cover developed by the University of Maryland²⁴ to select the appropriate land cover and the land cover change.

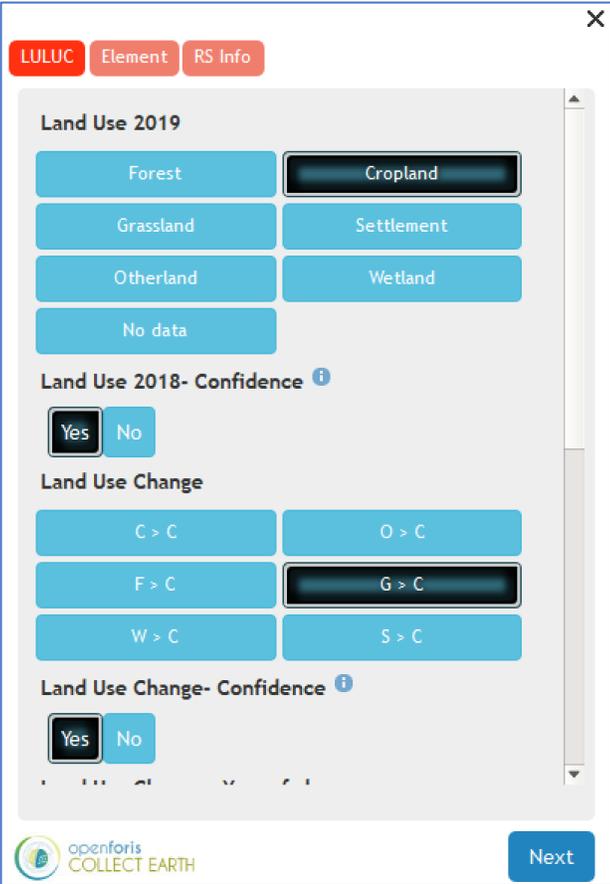

Example of the Collect Earth Survey	
Land use of 2019	
Type (IPCC) and subtype of land use	
Land use change	
Year of land use change	
Elements inside the plot	
Year of the image.	
	

Figure 8. Collect Earth survey used to carry out the spatial response

A reference label protocol was defined to avoid bias due to different interpretation criteria. Having a general approach to classify the land-use was a key factor to ensure all interpreters follow the same rules

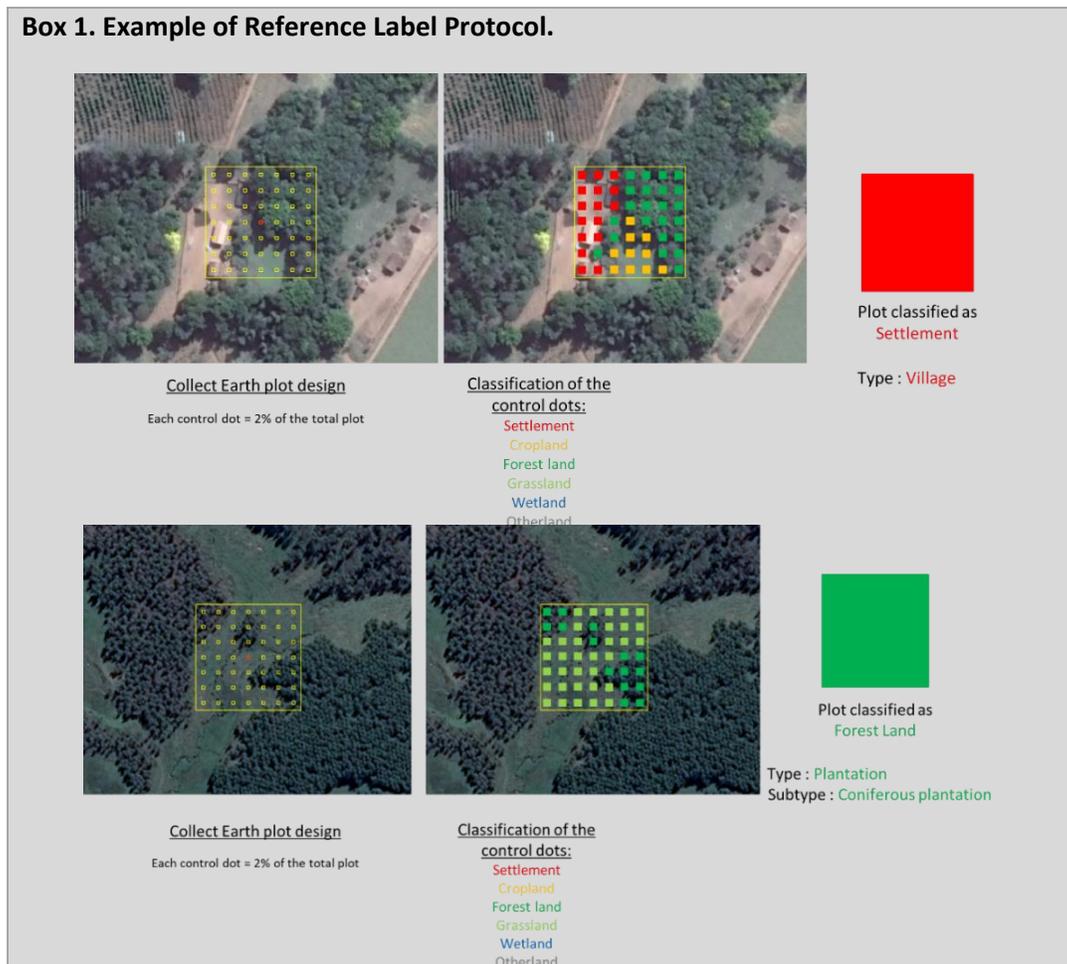

²⁴ The time-series of the Tree canopy cover and the Landsat spectral response of each plot is available in https://glad.umd.edu/Potapov/Cambodia/Samples_UNDP/index.html

to label the reference data, a hierarchy system was proposed, where if a minimum area inside the plot corresponding to the first category on the list, the plot will be labelled with this class. If the area was lower, the interpreter looks for the class on the list that covers the minimum area required. Following the IPCC good practices, Settlement and Cropland classes are above Forest, because both are anthropogenic land-use. The thresholds of the classes are detailed in Table 2.

Table 2. Reference label protocol hierarchy system and thresholds.

Class	Rank	Threshold
Settlement	1	20%
Cropland	2	20%
Forest	3	10%
Grassland	4	20%
Wetland	5	20%
Otherland	6	20%

Plot classified as Forest Land
Type : Plantation
Subtype : Coniferous plantation

3.3 ANALYSIS PROTOCOL

The analysis allows the conversion of the information contained in the comparison of the map and reference data into accuracy and area estimates. Most of the calculations are based on the error matrix, which contrasts the maps and the reference classification (FAO, 2016). The error matrix is a simple cross-tabulation of the class labels allocated by the classification of the map against the reference data for the sample plots, summarizing the results and quantifying the accuracy and area (Olofsson et al., 2014).

Since a systematic sampling design was used, the reference data absolute counts, n_{ij} , can be converted into estimated area proportions, \hat{p}_{ij} , using Equation 1:

Equation 1. Olofsson et al., 2014

$$\hat{p}_{ij} = W_i \frac{n_{ij}}{n_i}$$

Where \hat{p}_{ij} represents the proportion of area for the population that has map class i and reference class j , and W_i is the proportion of area classified as class i .

Together with information on accuracy and uncertainty (further discussed on the Uncertainty Analysis chapter), the error matrix provides the basis to adjust the area estimation obtained from the maps.

The estimation was based on the proportion of area derived from the reference classification, $p_{.k}$, because it is considered that should have smaller bias than the proportion mapped classification, p_k .

The estimator is the sum of the estimated area proportions of class k as determined from the reference classification (Equation 2).

Equation 2. Olofsson et al., 2014

$$\hat{p}_{.k} = \sum_{i=1}^q W_i \frac{n_{ik}}{n_i}$$

For the stratified estimator of a proportion of area (Equation 2), the standard error is estimated by:

Equation 3. Olofsson et al., 2014

$$S(\hat{p}_{.k}) = \sqrt{\sum_i \frac{W_i \hat{p}_{ik} - \hat{p}_{ik}^2}{n_i - 1}}$$

Where \hat{p}_{ik} is the sample count at cell i, k in the error matrix, W_i the area proportion of map class i , and the summation is over the q classes. The estimated area of class k is $\tilde{A}_k = A \times \hat{p}_{.k}$, where A is the total map area. The standard error of the estimated area is given by:

Equation 4. Olofsson et al., 2014

$$S(\hat{A}_{.k}) = A \times S(\hat{p}_{.k})$$

An approximate 95% confidence interval is obtained as $\tilde{A}_k \pm 1.96 \times S(\hat{A}_{.k})$

3.4 RESULTS

The result of labelling the samples and the quality control was stored in a central database and exported in excel format to the final analysis. To estimate AD, it was decided to use all available plots that correspond to the three-reference data grid collected during the Mapathon: 1) 4,921 plots corresponding to NFI grid, 2) 1,474 plots on an intensified sampling grid in a 4 km buffer from deforested areas in the 2015-2016 period, and 3) 2,522 plots on an intensified sampling grid within deforested areas in the period 2017-2018.

3.4.1 Integrating the samples with the expansion area map.

To integrate the information from different grids, it was necessary to carry out a pre-stratification. Thus, the first step was to weigh the total area of the country, using the map presented in Figure 6, into three first-order strata (pre-stratification), corresponding to the area covered by each grid. Then, the area for each land cover class in the map was calculated by strata, and the reference data was categorized by these first-order strata (grid).

As a result, each sample has a final class code as follow:

- 0: Sample in stable forest area*
- 1: Sample in an area high probability of change (2015-2016)*
- 2: Sample in an area high probability of change (2017-2018)*

3.4.2 Post-stratification

In a second step, the pre-stratified map was subdivided into the most representative Forest Types in Cambodia:

- Evergreen Forest,
- Semi-evergreen Forest,
- Deciduous Forest,
- Other Forests.²⁵

As a result of this stratification, 21 classes were created:

- Forest remaining Forest within strata 0, strata 1, and strata 2;
- Evergreen Deforestation within strata 0, strata 1, and strata 2;
- Semi-evergreen Deforestation within strata 0, strata 1, and strata 2;
- Deciduous Deforestation within strata 0, strata 1, and strata 2;
- Other Forest Deforestation within strata 0, strata 1, and strata 2;
- Non-Forest converted to Forest within strata 0, strata 1, and strata;²⁶
- Non-Forest remaining Non-Forest within strata 0, strata 1, and strata 2;

²⁵ Other forest types class aggregates the following sub-categories from FCC maps and Reference Data: Bamboo, Pine forest, Mangrove, Rear mangrove, Flooded Forest, Forest regrowth, Pine plantation, and Tree plantation.

²⁶ Non-Forest converted to Forest is included in the analysis in order to increase transparency and completeness. However, as explained in section 2.2, the REDD+ activity “enhancement of forest carbon stocks” was excluded from the FRL.

3.4.3 Estimation of accuracy, area and confidence intervals.

Overall accuracy of LCC Maps was 72.7% for 2011-2014, 77.5% for 2015-2016, and 76.8% for 2017-2018. Producer and user accuracy for stable lands (forest remaining forest and non-forest remaining non-forest) is within the range from 44% to 96% across all periods. In the case of deforestation highest user accuracy was 47.6% for deforestation of Evergreen forest in strata “1”, during the period 2010-2014. The highest producer accuracy was 53.3% for the same period and forest type.

The overall accuracy adjusted (to the proportion of area for each class), increases in all the periods: 80.0% for the period 2011-2014, 86.4% for 2015-2016, and 87.1% for 2017-2018. However, the producer accuracy was low in the cases of deforestation classes.

Based on proportion matrix analysis, the area for each class was recalculated and the Confidence Interval estimated. The estimated proportion area for each period is presented in tables 3, 4 and 5. These results demonstrate that the deforestation trend is decreasing in Cambodia. Detailed information on the error matrix, proportion matrix and variance matrix are presented in the Annex 1.

4 EMISSION FACTORS²⁷

Currently, Cambodia has not a National Forest Inventory to provide unbiased estimates of carbon stocks and Emission Factors (EF) at the national scale. However, as an alternative, most project-based forest inventory data has been collected by the government of Cambodia in partnership with different institutions providing estimates of forest biomass across the country (Sola, Vanna, Vesa, Van Rijn, & Henry, 2014).

In order to update the information presented in the First Reference Level, Cambodia collected new data to increase the quality of EF by forest type (Sola, Van Rijn, & So, 2019). Such information is the data source for the emission factors used in the Second FRL.

Data from all plots were harmonized by selecting relevant information from project files, adding forest type and wood density information, and estimating tree height and aboveground biomass with a common set of allometric equations.

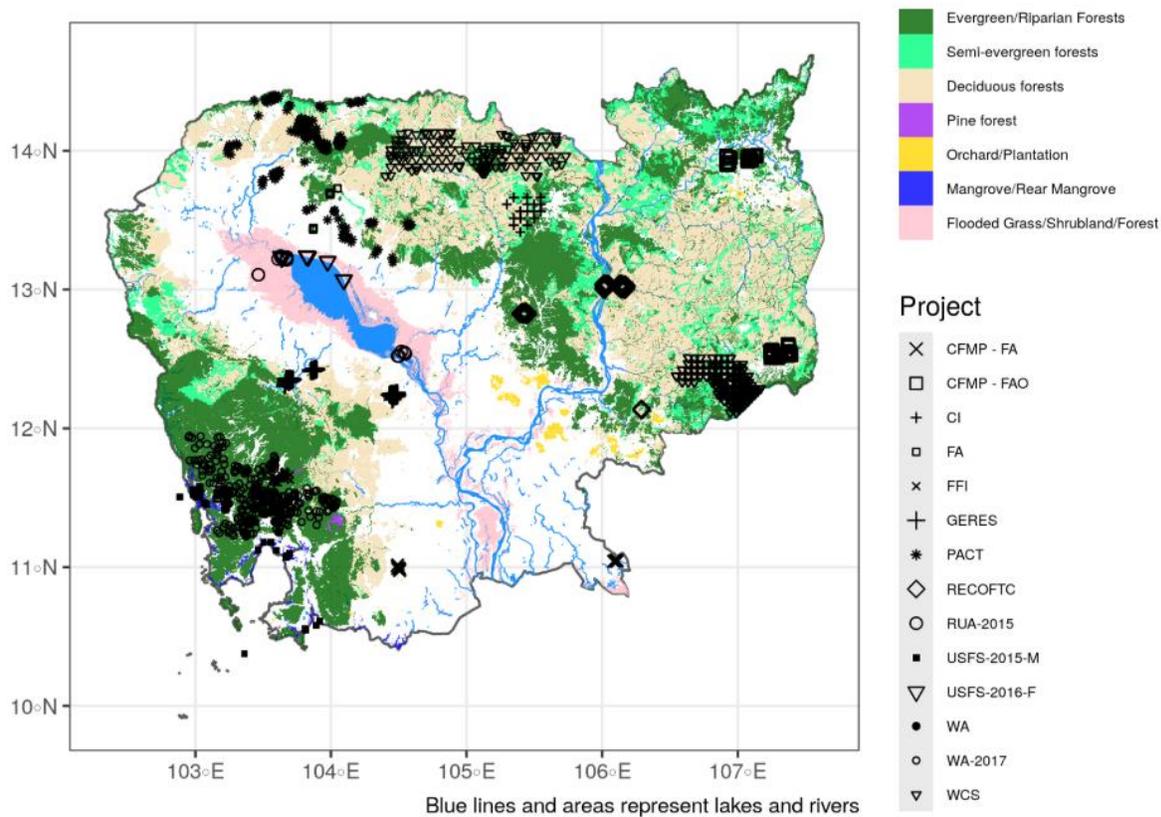

Figure 9. Distribution of forest inventory plots used to develop EF. Source: FAO 2019.

Table 6. Summary of existing forest inventory data in Cambodia.

The forest inventory data, detailed in Table 6 and Figure 9, was provided by the following institutions:

- Forest Administration (FA): 40 plots from the Permanent Sampling Plots (PSP) system in Koh Kong and Siem Reap provinces, and 40 plots from Community Forest (CF) projects located in Kampot and Svay Rieng provinces,
- Conservation International (CI): 51 plots from Prey Long REDD+ project.
- Wildlife Conservation Society (WCS): 57 plots from the Kulen Promtep Wildlife Sanctuary, 61 plots from Preah Vihear Protected Forest, 308 plots from the Seima REDD+ Project, and 15 plots from Cherndar logging company.
- Wildlife Alliance (WA): 105 plots from Southern Cardamoms REDD+ Project from 2014, and 247 plots from 2017.
- Fauna & Flora International (FFI): 71 plots from Siem Reap Community Forestry REDD+ project.
- Groupe Energies Renouvelables Et Solidarités (GERES): 349 plots from Community Forest Projects in Kampong Chnang and Pursat provinces.
- RECOFTC: 249 plots from Kratie and Kampong Thom provinces
- Pact International: 151 plots from Oddar Mancheay REDD+ project and 51 plots from Siem Reap provinces
- FAO: 218 plots from Community Forest projects in Kratie, Mondolkiri, Ratanakiri and Stung Treng provinces-
- Royal University of Agriculture (RUA): 18 plots collected in the Tonle Sap flooded forests.
- United States Forest Service (USGS): 48 plots collected on mangrove forests and 33 plots collected in the Tonle Sap flooded forests.

The 2007 vegetation map from MoE and the Land Use Map from 2016 were used to identify forest types at the plot level.

Wood density was added to the tree-level data based on species and genus averages from the Global Wood Density (GDW) Database ((Jerome Chave et al., 2009);(Zanne et al., n.d.)). The data from Southeast Asia and Southeast Asia Tropical were selected, and averages calculated for each species and genus. Wood density for each tree was based on species if available in the GWD, genus if species were not available, or a default value of 0.57 g/cm³ if both species and genus were unknown, not recorded or not in the data. The default value was based on a wood density average for Tropical Asia in Reyes et al. (Reyes, Gisela, Sandra Brown, Jonathan Chapman, 1992).

When not recorded in the field, tree height was estimated using forest type based allometric equations, developed with the other available data on tree H and DBH (Table 7).²⁸

Table 7. Developing tree height-diameter allometric equations.

Forest type 'mix'	Model
Community land	$H = 1.3 + 14.3706 * (1 - \exp(-0.0407 * DBH^{0.8198}))$
Deciduous	$H = 1.3 + 21.986 * (1 - \exp(-0.0407 * DBH^{0.8198}))$
Evergreen	$H = 1.3 + 29.9423 * (1 - \exp(-0.0407 * DBH^{0.8198}))$
Flooded forest	$H = 1.3 + 18.6158 * (1 - \exp(-0.0407 * DBH^{0.8198}))$
Mangrove	$H = 1.3 + 36.8175 * (1 - \exp(-0.0407 * DBH^{0.8198}))$
Semi-evergreen	$H = 1.3 + 29.0446 * (1 - \exp(-0.0407 * DBH^{0.8198}))$

Aboveground biomass was estimated using different allometric equations for different forest types or species for mangrove. The equation from Chave et al. (Jérôme Chave et al., 2014) was applied to evergreen forest, the equation developed in Cambodia for upland forest (Kim, Sola, et al. 2019) was used for semi-evergreen and deciduous forest, as well as community land and non-forest. The equation developed in Cambodia for flooded forest (Kim, S., S. Horn, T. So, G. Sola, 2019) was applied to flooded forest data and species-specific equations were applied to mangrove forest, based on the SWAMP protocol (Kauffman, J.B., 2012) and the report from USFS on the methodology to calculate mangrove carbon stock in Cambodia.

Trees' aboveground biomass was summed to plot level and converted to ton per hectare. Given that most projects covered different areas, a simple average was used. A 95 % confidence interval was calculated with the forest type average aboveground biomass. The carbon stocks were finally calculated as the sum of aboveground and belowground biomass multiplied by conversion factors:

Equation 5. Conversion from AGB to Carbon Stock

$$C_{\text{stock}} = \text{AGB} * (1 + \text{RS}) * \text{CF} * 44/12$$

Where:

- RS: Root-to-shoot ratio. Different root-to-shoot ratios were applied to the different forest types: 0.49 for mangrove (IPCC 2013), 0.37 for evergreen forest (IPCC 2006) and 0.2 for all other types (IPCC 2006).

²⁸ Further details in Annex 4

- CF: Carbon fraction, using the carbon fraction value 0.47 (IPCC 2006)
- 44/12: Atomic mass conversion from carbon to CO₂.

Table 8. Allometric equations applied to estimate Aboveground biomass.

Forest type	Equation
Evergreen	$AGB = 0.0673 * (DBH^2 * H * WD)^{0.976}$
Semi-evergreen	$AGB = 0.0607 * DBH^{2.2692} * H^{0.5122} * WD^{0.3183}$
Deciduous	$AGB = 0.0607 * DBH^{2.2692} * H^{0.5122} * WD^{0.3183}$
Community land	$AGB = 0.0607 * DBH^{2.2692} * H^{0.5122} * WD^{0.3183}$
Flooded forest	$AGB = 3238.2787 * (1 - \exp(-0.00000837 * (DBH^2 * H)))$
Mangrove	
Avicennia alba	$AGB = 0.1848 * DBH^{2.3524}$
Avicennia marina	$AGB = 0.1848 * DBH^{2.3524}$
Bruguiera cylindrica	$AGB = 0.0754 * WD * DBH^{2.505} + 0.0679 * DBH^{1.4914}$
Bruguiera gymnorhiza	$AGB = 0.0754 * WD * DBH^{2.505} + 0.0679 * DBH^{1.4914}$
Rhizophora apiculata	$AGB = 0.043 * DBH^{2.63}$
Rhizophora mucronata	$AGB = 0.043 * DBH^{2.63}$
Rhizophora sp.	$AGB = 0.043 * DBH^{2.63}$
Sonneratia alba	$AGB = 0.3814 * WD * DBH^{2.101} + 10^{(-1.1679 + 1.4914 * \log_{10}(DBH))}$
Sonneratia ovata	$AGB = 0.3814 * WD * DBH^{2.101} + 10^{(-1.1679 + 1.4914 * \log_{10}(DBH))}$
Xylocarpus granatum	$AGB = 0.3814 * WD * DBH^{2.101} + 10^{(-1.1679 + 1.4914 * \log_{10}(DBH))}$
Xylocarpus moluccensis	$AGB = 0.3814 * WD * DBH^{2.101} + 10^{(-1.1679 + 1.4914 * \log_{10}(DBH))}$
Other mangrove species	$AGB = 0.251 * WD * DBH^{2.46}$

4.1 Updated Emission Factors by forest class.

Based on the information described above the “table 4-4: Estimation of above-ground biomass (ton ha⁻¹) by forest types in Cambodia” of the first Forest Reference Level was updated as follow:

Table 9. Estimation of above-ground biomass (ton ha⁻¹) by forest types in Cambodia

Forest type	AGB ton ha ⁻¹	R	BGB	C ton ha ⁻¹ *	CO ₂ ton ha ⁻¹ **	Source
Evergreen forest	133.12	0.37	49.25	85.72	314.29	FAO 2019
Semi-evergreen forest	165.23	0.20	33.05	93.19	341.70	FAO 2019
Deciduous forest	70.87	0.20	14.17	39.97	146.56	FAO 2019
Forest regrowth	75.00	0.20	15.00	42.30	155.10	CFI (2008) cited in Sar (2010)
Flooded forest	79.73	0.20	15.95	44.97	164.88	FAO 2019
Tree plantation	100.00	0.20	20.00	56.40	206.80	IPCC (2003), MoE/UNDP (2003)
Pine plantation	100.00	0.20	20.00	56.40	206.80	IPCC (2003), MoE/UNDP (2003)
Mangrove	95.25	0.49	46.67	66.70	244.58	FAO 2019
Rear mangrove	165.00	0.49	80.85	115.55	423.68	Tran (2015)
Bamboo***	0.00	0.20	0.00	0.00	0.00	(Nil)

*0.47 was used as Carbon fraction (ton C /ton d.m.) from the default value in IPCC (2006b).

**One carbon equals 44/12 carbon dioxide.

***Bamboo=0, mean that area land cover represented bamboo class are very small

4.2 EFs used in the Second FRL.

To be aligned with the activity data's stratification the emission factors (EF) of Evergreen, Semi-evergreen, and Deciduous Forest were utilized in combination with Forest Types stratification of the activity data.

In the case of the class "Other Forest", the EF was derived from the weighted average of forest classes that had not enough samples in the activity data Table 10.

Table 10. forest type used to estimate the AGB and BGB for "Other Forest"

Class	11-14	15-16	17-18	Def Area Mean	Def Area %	AGB	BGB	C Stock	CO2	CI	SQ_prod CI Mean
Bamboo	3392.55	3202.02	2,059	2,885	7%	-	-	-	-	50%	-
Mangrove	447.26	628.79	34	370	1%	95	47	66.70	245	19%	0.163
Flooded forest	29270.12	5392.35	8,758	14,473	34%	80	16	44.97	165	17%	90.745
Forest regrowth	35741.52	20533.95	11,511	22,596	53%	75	15	42.30	155	50%	1,692.986
Pine forest	0.00	0.00	5	2	0%	100	20	56.40	207	50%	0.000
Pine plantation	0.00	55.31	3	19	0%	100	20	56.40	207	50%	0.002
Tree plantation	1349.71	2500.70	2,877	2,242	5%	100	20	56.40	207	50%	29.644
Total	70,201	32,313	25,247	42,587							

The final EFs used to construct the Forest Reference Level and its respective CI's are detailed in Table 11.

Table 11. Forest Types Deforestation National EF

Forest type	# plots	AGB	BGB	Total Biomass	Total Carbon	Total CO2e	CI (%)
Deciduous	132	70.87	14.17	85.04	39.97	146.55	10%
Evergreen	446	133.12	49.26	182.38	85.72	314.30	5%
Semi-evergreen	49	165.23	33.05	198.28	93.19	341.70	19%
Other Forest	54	73.03	14.85	87.88	41.30	151.43	0%

To obtain the EFs of "Other forest", the AGB and BGB values of each class were obtained by summing the products of the deforestation area and the biomass using the Equation 6:

Equation 6. sum of AGB and BGB

$$\sum_{Class}^{i} Biomass_i * (Def Area \%)_i$$

Where:

Biomass_i =above-ground biomass (AGB), below -ground biomass (BGB) of each class.

Def Area %_i = Proportion of the deforestation area of each class with respect to the total deforestation area.

To obtain the uncertainty, the Equation 7 was used

Equation 7. Eq. 3.2 IPCC 2006.

$$U_{\text{total}} = \sqrt{\frac{(U_1 * x_1)^2 + (U_2 * x_2)^2 + \dots + (U_n * x_n)^2}{|x_1 + x_2 + \dots + x_n|}}$$

Where:

U_{total} = the percentage uncertainty in the sum of the quantities (half the 95 percent confidence interval divided by the total (i.e., mean) and expressed as a percentage). This term 'uncertainty' is thus based upon the 95 percent confidence interval.

x_i and U_i = the uncertain quantities and the percentage uncertainties associated with them, respectively.

5 UNCERTAINTY ANALYSIS

Accuracy and precision of the FRL estimation are following analyzed, including the sources of non-systematic error or bias, and the precision of results based on the confidence interval of AD and EF.

5.1 SOURCES OF SYSTEMATIC ERROR

Several sources of systematic error or bias could affect the accuracy of the FRL. The most relevant sources identified has been the following:

Regarding AD, besides the error in the maps and its uncertainty, which was estimated and reported in the uncertainty propagation, the interpretation of reference data has been identified as the significant risk of bias.

During the collection of reference data, several interpreters analyze high spatial resolution satellite imagery from 2001 to 2019 to identify the land use and the land use changes.

Different criteria during the interpretation could provoke errors in the data collected. To minimize the potential error, a reference label protocol, described in the above section “Activity Data”, was implemented.

Further, a Quality Control procedure was established to avoid errors and to analyze mismatches during this activity. A random subset of 585 plots was independently assessed by three different interpreters, the overall average correspondence when the three interpreters agree on the classification was 79.7% (88.1% for the forest, and 66% for non-forest)., the overall average correspondence when there was an agreement between the interpreter and one reviewer was 97.9% (95.7% for the forest and 90.0% for non-forest).

In the case of the EF, the distribution of forest inventory was identified as the most critical risk of bias. As explained in the above section “Emission Factors”, Cambodia has not implemented an NFI yet, however, the country has managed to gather information from various local forest inventories associated with specific projects. Out of 627 inventory plots, used to estimate EF for the forest types of Evergreen, Semi-evergreen and Deciduous, 607 are located inside protected areas, which includes 358 plots inside REDD+ projects. Considering that, generally, 1) the forests located inside protected areas have a higher biomass density, and 2) the deforestation rate inside protected areas is notably lower than outside them, hence, there is a high risk of oversized EFs and, therefore, overestimating emissions. To minimize the overestimation risk, as explained above, plots collected from the very high-value forest were removed from the final forest carbon stocks.

Another important element related to the EF’s bias is the information missed or not collected due to the different forest inventory methods applied. To apply the allometric equation used in the EF’s estimation, information from diameter at the breast height (DBH) and tree height is needed. However, several collected data do not include information on tree height. When this information is missed, an H-D model by forest type was developed and applied, using information from 8059 trees for model development and 4035 trees for validation. The model had a 17% bias overall and less than 20% bias in all forest type classes.

Table 12. The bias of the H-D models.

Forest Type	Bias (%)
Evergreen	18
Deciduous	15
Semi-evergreen	17
Overall	17

5.2 UNCERTAINTY PROPAGATION

Confidence Intervals for AD and EFs developed to estimate the FRL were evaluated and reported in their corresponding sections. Then Confidence Interval were combined to propagate the uncertainty. Uncertainty propagation was developed following Approach 1 from IPCC (2006). The Approach 1 analysis estimates uncertainties by using the error propagation equation in two steps:

In the first step the Equation 8. Eq. 3.1 from IPCC (2006) is used to combine emission factor and activity data.

Equation 8. Eq. 3.1 IPCC, 2006.

$$U_{\text{total}} = \sqrt{U_1^2 + U_2^2 + \dots + U_n^2}$$

Where:

U_{total} = the percentage uncertainty in the product of the quantities (half the 95 percent confidence interval divided by the total and expressed as a percentage);

U_i = the percentage uncertainties associated with each of the quantities.

In the second step the Equation 3.2 from IPCC (2006) is used to arrive at the overall uncertainty.

Equation 9. Eq. 3.2 IPCC 2006.

$$U_{\text{total}} = \sqrt{\frac{(U_1 * x_1)^2 + (U_2 * x_2)^2 + \dots + (U_n * x_n)^2}{|x_1 + x_2 + \dots + x_n|}}$$

Where:

U_{total} = the percentage uncertainty in the sum of the quantities (half the 95 percent confidence interval divided by the total (i.e., mean) and expressed as a percentage). This term 'uncertainty' is thus based upon the 95 percent confidence interval.

x_i and U_i = the uncertain quantities and the percentage uncertainties associated with them, respectively.

Results by periods, strata, and propagation are presented together with the Second FRL options in the following section.

6 FRL RESULT

The Second FRL of Cambodia is calculated as the average of annual emissions during the reference period: **60,257,501 t CO₂eq/year ±11.07%**.

The combination of AD and EF allow estimating annual emissions summarized in Table 13 and Figure 10

Table 13. Forest Reference Emission Level by option in Ton CO₂eq year

YEAR	Emissions by Deforestation (t CO ₂ e)	Uncertainty (%)
2011	71,840,311	9.40%
2012	71,840,311	9.40%
2013	71,840,311	9.40%
2014	71,840,311	9.40%
2015	56,818,352	12.14%
2016	56,818,352	12.14%
2017	40,531,030	15.51%
2018	40,531,030	15.51%
FREL	60,257,501	11.07%

** This activity is excluded in the modified FRL submission.*

Results demonstrate that deforestation has declined during 2014-2018 in Cambodia since a peak in deforestation was estimated during 2010-2014. The results are based on the enhancement of both the accuracy and improvement of the national data through improved methods and new data compared with first FREL, for AD and EF estimates. The decline in deforestation during 2014-2018 could relate to the development and implementation of policies and strategies undertaken by Cambodia as described in the NRS.

The low increment of the uncertainty from the period 2010-2014 to the periods 2014-2016 and 2016-2018 is related to the changes in deforestation estimates. As explained above, in the sampling design of the reference data section, while in period 2010-2014 the rate was 1 plot per 2,381 ha deforested, in the later periods the rate was 1 plot per 601 ha (2014-2016) and 644 ha (2016-2018) deforested, respectively.

Thus, the probability to find an error and, therefore, the uncertainty was lower in the period 2010-2014. In future submissions, Cambodia plans to improve uncertainty estimates.

7 SUMMARY RESULTS

MAIN FEATURES OF THE FRL	
Proposed FRL	60,257,501 tCO₂eq/year
Period	2011 – 2018
Uncertainty (%)	11.07 %
Type and duration of FRL	FRL based on historical average emissions from 2011 to 2018
Adjustment for national circumstances	No
Scope	National FRL for the entire national territory
Activities included	Deforestation
Pools included	Above-ground biomass (AGB) and below-ground biomass (BGB). <i>Litter, deadwood, and soil organic carbon are excluded due to the lack of data.</i>
Gases included	CO ₂
Activity Data	Stratify Area Estimator method is applied.
Emission Factors	Estimated by several existing forest inventories in the country. EF by forest types were: <ul style="list-style-type: none"> • Evergreen forest: 314.30 • Semi-evergreen forest: 341.70 • Deciduous forest: 146.55 • Other forests: 151.43

8 AREAS OF IMPROVEMENT

This National FRL has included several improvements compared with the National FRL submitted in 2017:

- The activity data method has been modified to include in the report the best existing information in the country and to provide the information required to timely report uncertainty. The first FRL was constructed based on the pixel count method which provided a single area estimate for each land cover class without an estimate of confidence interval. In the construction of the second FRL, the SAE approach was used to estimate the area of each class, providing information on confidence intervals. The SAE approach helped to estimate the global accuracy of the second FRL that was not possible to do during the first submission.
- EF's have been refined and analyzed with greater rigor to avoid, as far as possible, the over or underestimation of emissions.
 - Calculation and protocols have been updated, and new data has been integrated.
 - Biomass models for flooded forest and upland forest (multi-species models for deciduous forest) were developed.
 - Two technical reports on developing emission and removal factors for flooded forest in the Tonle Sap region and upland forest were created.
- Uncertainty analysis, including the uncertainty propagation and the description of sources of systematic error, has been included.

However, some areas for further technical improvement identified in the FRL Technical Assessment Report from 2017 has not been addressed yet:

- The country has not implemented the NFI to improve the national EFs.
- New data, methods and protocols need to be implemented and developed to report excluded REDD+ activities.
- The country needs to collect data on litter, deadwood, and soil organic carbon pools to be included in the next FRL.
- Non-CO₂ gases have not been included in the Second FRL. Currently, Cambodia is working on the Fire Alert System which will analyze the current and historic alerts of wildfires. This will allow Cambodia to include Non-CO₂ gases in the next FRL.

As priority considerations in the next FRL, the Government of Cambodia has plans to add two more REDD+ activities - forest degradation and enhancement (conversion from non-forest to forest) and has plans to improve the estimates of EFs.

Annex 2. Description of land use/cover types.

No.	Land cover class	ID	Description
1	Evergreen forest	E	Areas covered by trees maintaining their leaves during the whole year.
2	Semi-evergreen forest	Se	Contain variable percentages of evergreen and deciduous trees.
3	Deciduous forest	D	Comprised of dry mixed deciduous forest and dry Dipterocarp forests
4	Bamboo	B	Areas dominated by bamboo
5	Wood shrub	Ws	Areas dominated by evergreen and deciduous woodland with a height less than 5 meters
6	Mangrove forest	M	Areas dominated by Mangroves i.e. coastal salt tolerant species
7	Rear Mangrove	Mr	Mostly growing in coastal zone after mangrove spp. Salt tolerant species but only infrequent floods
8	Rubber plantation	Rp	Areas currently supporting, and areas reserved for, rubber plantation
9	Flooded Forest	Ff	This forest type is found in Tonle Sap Lake. Most of the forests are low and disturbed. In many cases, there is only a mosaic remaining
10	Forest Regrowth	Fr	<p>Areas of naturally regenerated forest where there are clearly visible indication of human activities such as selective logging, areas regenerating following agricultural land use, areas recovering from human induced fire, etc.</p> <ul style="list-style-type: none"> -Include forest where it is not possible to distinguish whether planted or naturally regeneration. -Include forests with mix of naturally regenerated trees and planted/seeded trees, and where the naturally regenerated trees are expected to constitute more than 50 percent of the growing stock at stand maturity. -Include abandoned forest land and bare land which will regrow into forest within ten years
11	Pine Tree	P	The area dominated by coniferous trees
12	Pine plantation	Pp	The area dominated by pine tree plantation
13	Oil palm	Po	The area dominated by oil palm tree.
14	Tree plantation	Tp	This class includes the following type: teak, eucalyptus, acacia, jatropha and others.
15	Paddy Field	Hr	Paddy field is a flooded parcel of arable land used for growing semiaquatic rice
16	Crop Land	Hc	This category includes arable and tillage land, and agro-forestry systems where vegetation falls below the thresholds used for the forest land category
17	Grassland	G	Grasslands are characterized as lands dominated by grasses rather than large shrubs or trees. It is crucial that the rainfall is concentrated in six or eight months of the year, followed by a long period of drought when fires can occur
18	Built-up area	Bu	The patch of land with building and construction
19	Village	Bt	The patch of land with houses and garden surrounding house.
20	Rock	Rp	Land of naturally exposed rocks or strip mines, quarries and gravel pits.
21	Sand	S	In general, land of sand having thin soil or sand including deserts, dry salt flats, beaches, sand dunes.
22	Water	W	Area of fresh and sea water

Annex 3. Detailed methodology for acquiring activity data.

1. Land Use/ Cover 2016 map

The LULC 2016 map was prepared by MRV team of the General Directorate Administration for Nature Conservation and Protection (GDANCP / MOE) corporately with Forest Administration (FA), using Landsat imagery. The process included segmentation based on the LULC 2014 map and PCA from both 2014 and 2016 imagery to extract potential areas of change. This resulted in consistent polygons over time. The polygons were subsequently visually classified for the areas of change. Land use and Land cover 2016 were generated within 22 categories, in which forest classes have fallen under 13 categories and non-forest were in 9 categories with a minimum mapping 5ha. The procedure for 2016 mapping is explained in the Figure 11.

In the mosaicking of LANDSAT images, all LANDSAT images were masked to remove cloud and haze covered and these masked images were mosaicked together. In the case of 2016, a total of 52 LANDSAT surface reflectance images were masked and these masked images were mosaicked to create 2016 LANDSAT mosaic.

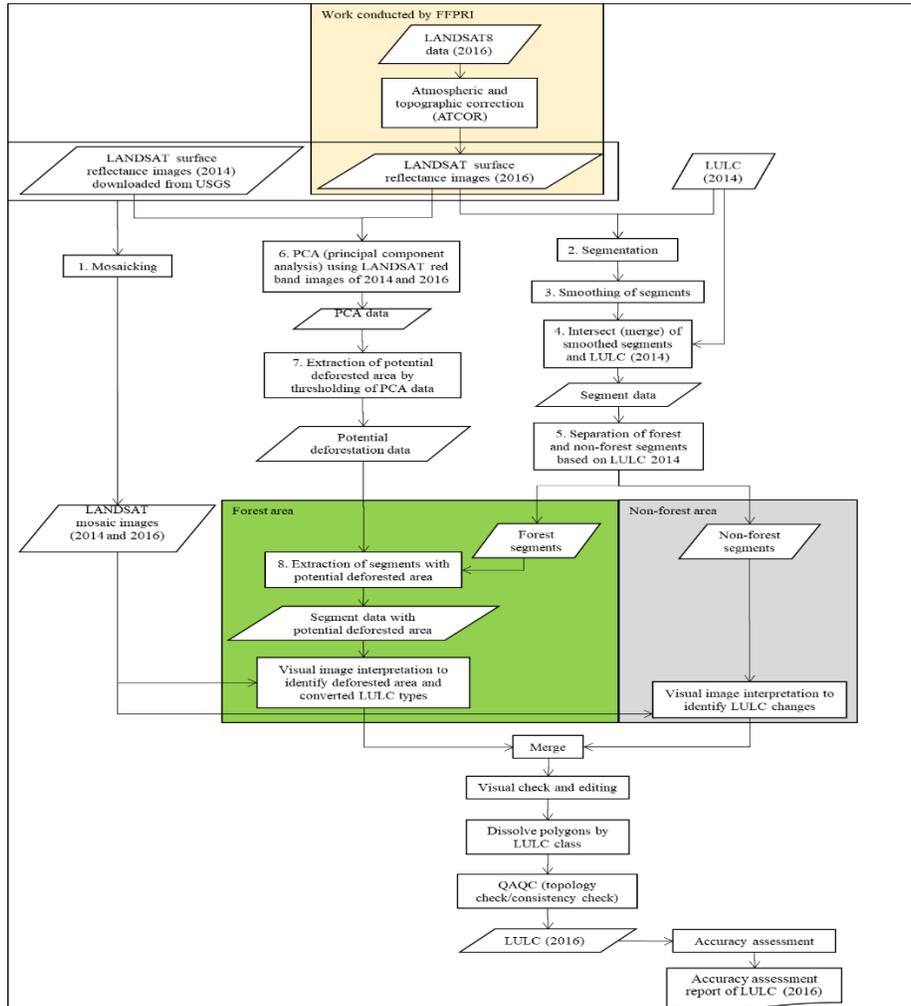

Figure 11 The procedure for LULC 2016 map

Quality assurance and Quality Control (QA/QC)

QA (Quality Assurance)/QC (Quality Control) work was conducted to extract and check potential classification errors. First both 2014 and 2016 forest classes were grouped into permanent and temporary forest classes. Then, unlikely land use/cover conversions between 2014 and 2016 were extracted. All the extracted polygons were manually inspected by the expert image interpreters.

Grouping of 2014 and 2016 forest classes into permanent and temporary forest classes

Permanent forest classes (PF)	Temporary forest classes (TF)
Evergreen forest (E)	Forest regrowth (Fr)
Semi-evergreen forest (Se)	Tree plantation (Tp)
Pine forest (P)	Rubber plantation (Rp)
Deciduous forest (D)	Oil palm plantation (Po)
Mangrove (M)	Pine plantation (pp)
Rear Mangrove(Mr)	
Flooded forest (Ff)	
Bamboo (B)	

Extraction of unlikely land use/cover conversions

2014	2016	Unlikeliness	No. of polygon
NF	PF	Unlikely	1070
TF	PF	Unlikely	15
PF	TF	Likely but rare	2719
PF	PF	Check only forest types in 2014 and 2016 are different	158

All the extracted polygons were checked and corrected (if necessary) by re-interpretation of LANDSAT images by expert image interpreters.

Accuracy assessment and Area Estimation

Accuracy assessment of 2016 LULC was conducted using FAO SEPAL system. Reference sample for accuracy assessment were generated by using SEPAL’s stratified area estimation tool.

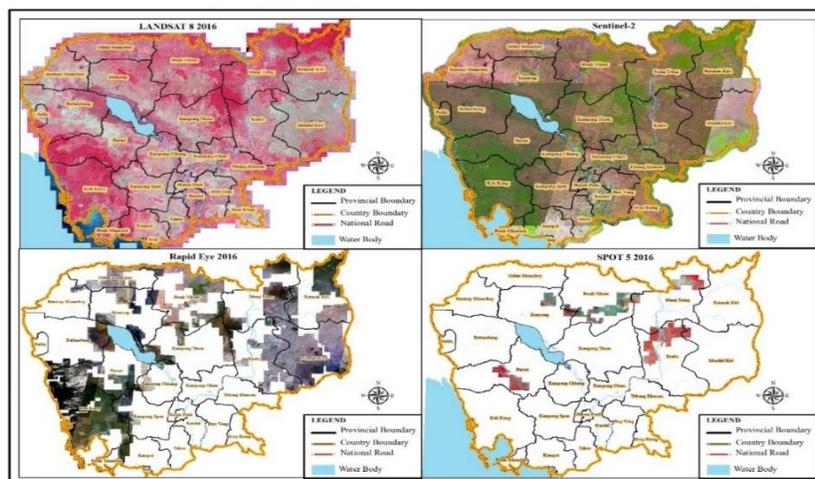

Figure 12. Satellite imageries used for classification and accuracy assessment of forest cover 2016

The accuracy assessment of land use/cover data was carried out into two separate steps through ground truth and verification of data from RapidEye, SPOT5, and Sentinel-2 and images from Google Earth for

verification of land use/cover classification with 1651 verified points covering 25 capital-provinces nationwide.

Accuracy Assessment was done in collaboration with national and international experts including from FAO-UNREDD, JICA-CAMREDD and international universities with the Overall Accuracy of LULC map is 84.92 % and the overall accuracy adjusted (to the proportion of area for each class) increase up to 87.48%.

2. Land Use/ cover 2018 map

The LULC 2018 map was prepared by MRV team of the General Directorate Administration for Nature Conservation and Protection (GDANCP / MOE) corporately with Forest Administration (FA), using Landsat imagery. The process includes LULC 2016 created based on segmentation method, PCA automatic change detection method using 2016 and 2018 Landsat mosaics to extract potential areas of change, and GLAD forest cover loss to identify the degree of deforestation potential. The procedure for 2018 mapping is explained in the next figure.

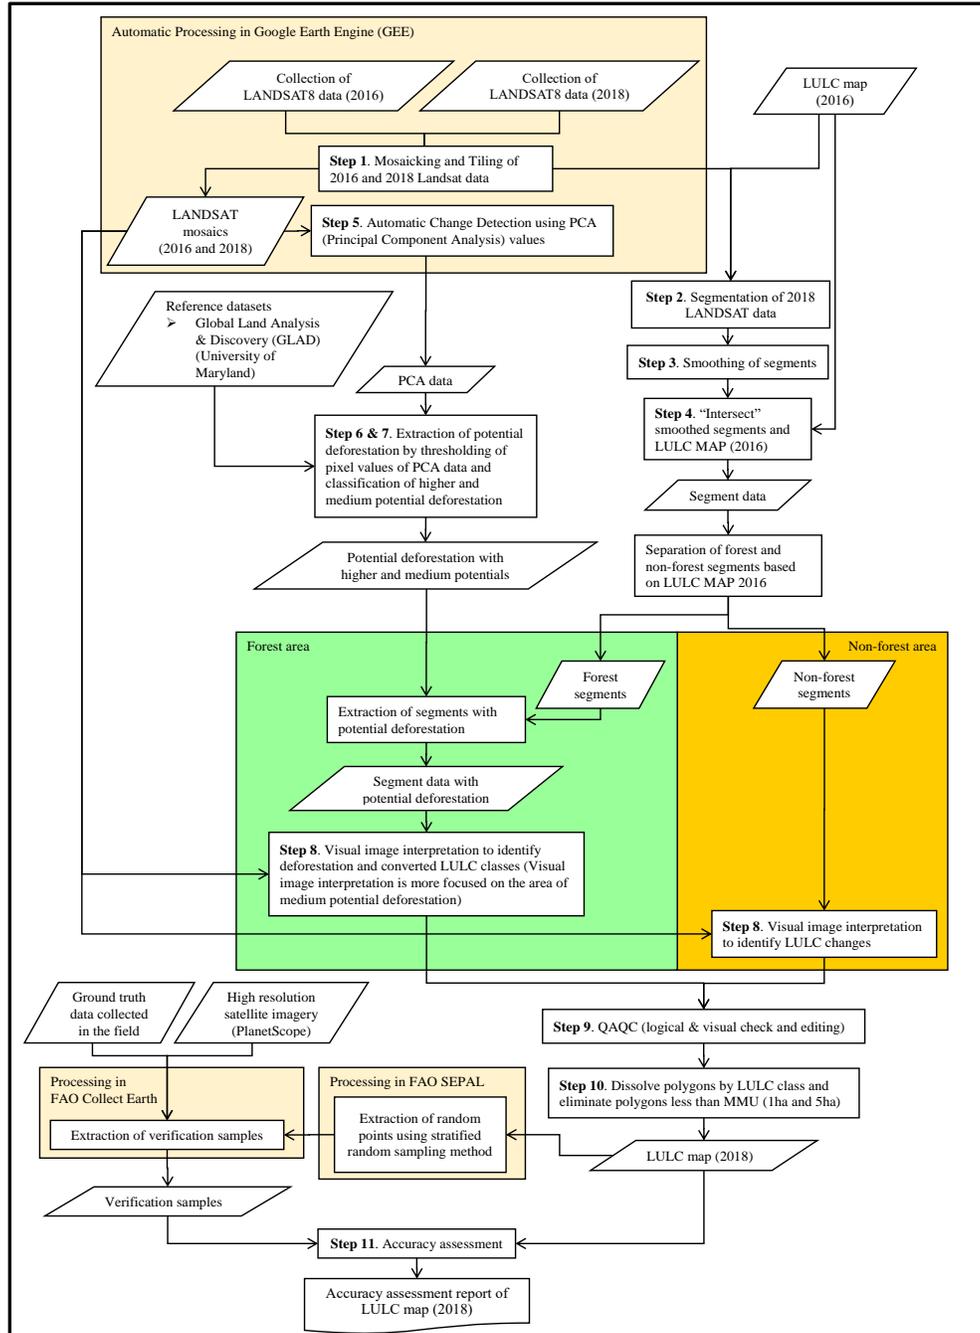

Figure 15. The procedure for LULC 2018 map

Quality Assurance and Quality Control (QA/QC)

QA (Quality Assurance)/QC (Quality Control) work was conducted to extract and check potential classification errors. First 2014, 2016 and 2018 LULC classes were grouped into permanent forest (PF), temporary forest (TF) and non-forest classes. Then, unlikely LULC changes between 2014 -2016 and 2016-2018 were extracted. All the extracted polygons were manually inspected by the expert image interpreters.

Grouping of 2014, 2016 and 2018 LULC classes into permanent and temporary forest classes and non-forest classes

Permanent Forest (PF)	Temporary Forest (TF)	Non-forest (NF)
Evergreen forest (E)	Forest regrowth (Fr)	Crop land (Hc)
Semi-evergreen forest (Se)	Tree plantation (Tp)	Paddy field (Hr)
Pine forest (P)	Rubber plantation (Rp)	Grassland (G)
Deciduous forest (D)	Oil palm plantation (Po)*	Wood shrub (Ws)
Mangrove (M)	Pine plantation (Pp)*	Water (W)
Rear mangrove (Mr)		Built-up area (Bu)
Flooded forest (Ff)		Village (Bt)
Bamboo (B)		Rock (R)
		Sand (S)

* It should be noted that in the national LULC class of Cambodia, Oil Palm Plantation (Po) and Pine Plantation (Pp) are grouped into NF, but these were grouped into TF in QA/QC because these two also appears as forest on satellite imagery.

Extraction of unlikely LULC changes

2014	2016	2018	Unlikelihood
PF	NF	PF	Unlikely
TF	NF	PF	Unlikely
NF	PF	NF	Unlikely
NF	NF	PF	Unlikely
NF	PF	PF	Unlikely
NF	PF	TF	Unlikely
PF	TF	PF	Unlikely
TF	TF	PF	Unlikely
TF	PF	PF	Unlikely
TF	PF	TF	Unlikely
PF	PF	TF	Likely but rare
PF	PF	PF	Check the inconsistent forest classes of 2014, 2016 and 2018.

All the extracted polygons were inspected and corrected (if necessary) by re-interpretation of LANDSAT images by expert image interpreters.

Extraction of unlikely land use/cover conversions

2014	2016	2018	Unlikelihood	No. of polygon
PF	NF	PF	Unlikely	88
TF	NF	PF	Unlikely	3
NF	PF	NF	Unlikely	75
NF	NF	PF	Unlikely	201
NF	PF	TF	Unlikely	5
PF	TF	PF	Unlikely	1
TF	TF	PF	Unlikely	9
TF	PF	TF	Unlikely	5
PF	PF	TF	Likely but rare	149
PF	PF	PF	Check only forest types in 2014, 2016 and 2018 are different	87

All the extracted polygons were checked and corrected (if necessary) by re-interpretation of LANDSAT images by expert image interpreters.

Accuracy assessment and Area Estimation

The accuracy assessment and area estimation of 2018 LULC was conducted using the same procedure as LULC 2016. The total of 1055 points were distributed among 6 operators from the MRV team and international consultant AAS for visual interpretation using Very High-Resolution imagery present in Google Earth and time series of Landsat, Sentinel-II.

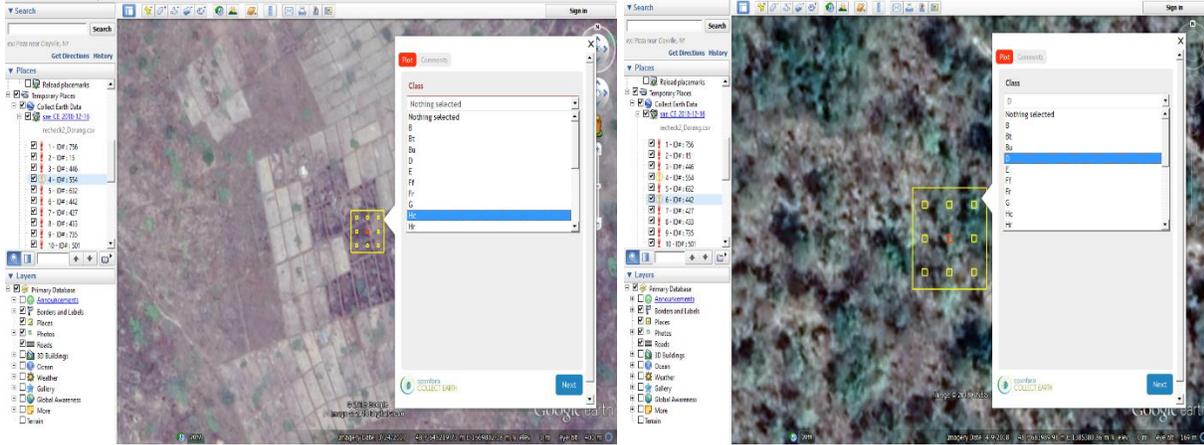

Figure 16. Interpretation of randome point in Google Earth

The team for field check was divided in four teams: First team responsible for 133 sample points that covered the 6 provinces, Second team was responsible for 131 sample points in 6 provinces, Third team was in charge of 137 sample points in 7 provinces and the Fourth team was responsible of 137 sample points in 4 provinces. To cover all the sample points, the teams spent approximately 12 days in the field.

Summary of random sample point assess by province

No	Province	No.Point	No	Province	No.Point
1	Kampong Spueu	16	13	Kampong Thom	32
2	Kaoh Kong	27	14	Preah Vihear	32
3	Krong Preah Sihanouk	8	15	Otdar Mean Chey	18
4	Palin	8	16	Banteay Mean Chey	28
5	Kampot	7	17	Siem Reap	34
6	Takaev	8	18	Stueng Traeng	17
7	Kandal	15	19	Kratie	24
8	Bat Dambang	31	20	Mondol Kiri	20
9	Pousat	27	21	Rotanakiri	20
10	Kampong Chhnang	11	22	Prey Veang	35
11	Phnom Penh	18	23	Svay Rieng	21
12	Kampong Cham	33	TOTAL		212
